TABLE OF CONTENTS

Table of Contents 3

Foreword by A. ROCA-ROSELL 12

Committees 14

E. NICOLAIDIS: Science and the Eastern Orthodox Church during the 17th-19th Centuries 17

The Different Historiographies of Science. Their Advantages and Shortcomings 26

M. KOKOWSKI: The Different Strategies in Historiography of Science. Tensions between Professional Research and Postmodern Ignorance 27

C. D. SKORDOULIS: Epistemological Aspects of Historiography of Science in Greece 34

M. T. BORGATO: On the Historiography of Mathematics in Italy 40

Cross-National and Comparative History of Science Education 46

K. TAMPAKIS: Two Worlds Apart –Comparing Greek and American 19th Century Science Education 47

S. VALERIANI, M. ISHIZU: Knowledge Diffusion and the Learning of Practical Knowledge: Case Studies of Early Modern Japan and Europe 53

M. ISHIZU, T. XU, A. SINGH: Knowledge Transfer and the Jesuits: Comparative Case Studies of Early Modern Japan, China, and India 59

S. ONGHENA: A mediator between different nations? The introduction of laboratory instruction in science curricula of secondary education in Belgium and Germany (1880-1914) 65

The History of Science and Education 71

P. HEERING, S. KOWALSKI: Not out of the Blue –the Genesis of Modern School Science Textbook Descriptions of Historical Experiments 72

I. GUEVARA-CASANOVA: Visual Aids in The Nine Chapters on the Mathematical Art: Connections between Geometry and Algebra in Secondary School 78

M. TERDIMOU The Reception of Mathematical Knowledge through European Textbooks by the Greek Intellectual Community in the 18th Century 90

P. SAVATON: History of Sciences and the Teaching of Life and Earth Sciences in French Secondary School. What Kind of Teacher's Training and What Kind of Teaching? 97

H. FERRIÈRE: Why can it be Difficult, Especially for Biology Teachers, to Use On-line Resources in History of Science for Inquiry-based Science Teaching? 102

I. L. BATISTA: Teaching Scientific Explanations and Theories from a Methodological Association of Historical-Philosophical Structure and Pedagogical Goals 107

M. CASTELLS, A. KONSTANTINIDOU: Understanding of pre-Galilean Motion Trajectory by Present Day Students. Can an Ancient Obstacle be Overcome by our Students? 117

C. ZARAGOZA DOMÈNECH, C. MANS, J. M. FERNÁNDEZ-NOVELL: More History of Chemistry, more Interest in Science 125

S. K. SAHA: The Origins of Technical Education in India: Study of Different Approaches 132

S. VALLMITJANA: Early Scientific Instruments for Teaching Physics in the University of Barcelona 140

P. LAUGINIE: Les Magiciens de la Lumière (Wizards of Light): A Film for Education 148
L. MAURINES, D. BEAUFILS: An Aim for Scientific Education in France: the Image of the Nature of Science. The Contribution of the History of Science in Physics Courses 155
D. M. FARÍAS, M. CASTELLS, J. CASTELLÓ: How to Read the History of Science in Science School Textbooks from a Sociological Perspective: Theoretical and Methodological Considerations Inspired by the Ideas of Bruno Latour about Non-humans and Networks 165

Centres and Periphery in Europe: The STEP Research Project 174
G. VANPAEMEL: Laboratory Cultures in Europe. The 'German Model' in the European Periphery 175
J. SEKERÁK: Centres and Peripheries in Europe: The Case of Gregor Mendel's Discovery 181

Circulation of Ideas, Techniques and Scientific Personae. –the Role Networks did Play, from the Gender Perspective 186
M. BURGUETE: Studies of Medicine from the Gender Perspective 187
F. BUJOSA, G. GALLEGO-CAMINERO, P. SALAS, J. MERCANT, J. M. PUJADES, J. MARCH, J. P. D'ELIOS: Exchange of Scientific Information between the Sanitary Professionals Participating in the International Sanitary Conferences in the 19th Century... 194
P. ZELLER: Naturalistic Observations in Apulia during the 19th Century. Vincenzo De Romita and Enrico Hillyer Giglioli 200
F. SEEBACHER: Erna Lesky, General and Diplomat. Networking as a Power Tool for the History of Medicine... 208
O. Yu. ELINA: How Could Russian Intellectual Women Contribute to Agriculture? –Circulation of Ideas in Education and Career Development of Women Agronomists, Late 19th - Early 20th Century.. 217
I. DELGADO ECHEVARRÍA, C. MAGALLÓN PORTOLÉS: International Networks for Supporting Scientific Careers of Women in Spain, in the First Third of the 20th Century.................................. 224

Knowledge and Technology in the Mediterranean Basin 232
J. SÁNCHEZ MIÑANA: Bell's Travels to Paris and the Introduction of his Telephone into France (1877-78) 233
M. GATTO: The ram-tortoise of Hegetor of Byzantium in the Treatise On Machines by Atheneaus Mechanicus. Some remarks on its reconstruction 240
A. F. CONDE: Alentejo (Portugal) and the Scientific Expertise in Fortification in the Modern Period: the Circulation of Masters and Ideas 246
J. VALENTINES ÁLVAREZ: The technocrats against "Technocracy": Motorways and Bottlenecks in Engineering Ideologies 253

The Transmission of Mathematical Sciences among the Mediterranean Cultures 258
V. GAVAGNA: Francesco Maurolico and the Restoration of Euclid in the Renaissance 259
G. DE YOUNG: Playfair's Geometry Crosses the Mediterranean: Translation of an English Geometry Textbook into Arabic 265
K. NIKOLANTONAKIS: Studies on the Problem of Minimum and Maximum in Conic Sections' Traditions. Apollonios of Perga and Serenos of Antinoeia.. 272
G. KATSIAMPOURA: Astronomy in Late Byzantine Era: A Debate between Different Traditions 281

The Travels of Scientists in Europe since the 16th Century 287
T. N. CARVALHO: Invisible Travellers and Virtual Tracks: Knowledge Construction in Colóquios dos Simples e Drogas de India... of Garcia de Orta (Goa, 1563) 288
P. D. OMODEO: The German and European Network of the Professors of Mathematics at Helmstedt in the Sixteenth Century 294
S. DÉBARBAT: Voyages along Meridian Lines in Europe 302

Y. TAKIGAWA: Contribution of Japanese Printed Drawings of Aquatic Animals Brought to Europe by Holland Merchants in the 18th and 19th Centuries for Biological Development 308
A. J. MACKOVÁ: Jaroslav Petrbok and František Lexa –Orient and the Balkan Peninsula Travels 313
M. GROS: European Voyages around the Lapland Expedition (1736 -1737).. 322

Within Europe and beyond Europe: the Jesuits as Circulators of Science 327
A. UDÍAS: Mathematics in the Jesuit Colleges in Spain in the 17th and 18th Centuries 328
K. VERMEIR: Optical Instruments in the Service of God. Light Metaphors for the Circulation of Jesuit Knowledge in China 333
M. ELAZAR: The Jesuit Honoré Fabri and the Theory of Projectiles 338
B. HOPPE: The First Protestant Missionaries as European Naturalists in India –Competitors of the Jesuits in the 18th Century 344
C. FAUSTMANN: "In parte physicae theoretica Newtonum eiusque commentatores secutus sum" – Leopold Gottlieb Biwald's Physica Generalis as a Compendium Propagating Newtonian Physics in Europe 349
S. J. JUZNIC: Hallerstein and Gruber's Scientific Heritage 355

Cartesian Physics (as Experimental Philosophy) and its University Reception 371
D. BELLIS: An Epistolary Lab: The Case of Parhelia and Halos in Descartes' Correspondence (1629-1630) 372
E. VAMPOULIS: The Empirical Element in Descartes' Physics and its Reception by Spinoza 378
T. NYDEN: Experiment in Cartesian Courses: The Case of Professor Buchard de Volder 384
M. DOBRE: Rohault's Traité de Physique and its Newtonian Reception 389

Some Aspects of the Circulation of Symbolic Language 395
F. ROMERO VALLHONESTA: The Circulation of Algebraic Symbolism Related to the First Algebraic Works in the Iberian Peninsula 396
M. R. MASSA-ESTEVE: The Circulation of Symbolic Language in the Seventeenth Century 405
N. HUYGHUES DES ETAGES: Mathematics and Instrumentalization as "Linguistic" Tools for the Widespread Circulation of Science and Technology 415

The Development of New Scientific Ideas in Portugal and Other Peripheral Countries: Scientists, Laboratories, Instruments and Texts in the Nineteenth and Twentieth Centuries 419
P. COSTA, H. I. CHAMINÉ, P. M. CALLAPEZ: The Role of Theodor Gerdorf, Friedrich Krantz and Émile Deyrolle in the Collections of Mining, Metallurgy, Mineralogy and Paleontology from the School of Engineering (ISEP) of the Porto Polytechnic, Portugal 420
F. VIEGAS: The Scientific Life of Marieta da Silveira 429

FOREWORD

It gives me great pleasure to present the proceedings of the 4th International Conference of the European Society for the History of Science (ESHS), which was held in Barcelona between 18 and 20 November 2010. The ESHS, founded in 2003 in Paris, has become one of the most important reference points for our subject not only in Europe but also in the world[1]. The large number of papers presented for the Barcelona Conference, and the wide range of subjects bear witness to this fact.

The Barcelona Conference was organized jointly with the Catalan Society for the History of Science and Technology (Societat Catalana d'Història de la Ciència i de la Tècnica, SCHCT), a society affiliated to the Institute for Catalan Studies (Institut d'Estudis Catalans, IEC). More than a century after its creation, the IEC has become the main academic institution for higher culture and research in the Catalan speaking regions. The SCHCT was founded in 1991 and its function is to promote history of science and technology through publications, regular sessions and general meetings. The 4th Conference coincided with the XI Trobada of the SCHCT. On the 21st November, additional sessions took place, including a plenary lecture and the annual general assembly.

The aim of the Barcelona Conference was to facilitate the presentation of a variety of research topics and perspectives. Our logo represents: a) the medieval shipyards of the city (Drassanes), b) the Industrial School of Barcelona, c) the Hospital of la Santa Creu i Sant Pau, d) the Fabra Observatory, and e) the chimneys of the industrialized city. All this sums up the history of Barcelona, with its roots in medieval times, and its strong tradition of scientific, technical and medical activities.

I wish to express my sincere gratitude to all the persons and institutions for making this meeting possible. We obtained support from several universities (UPC, UAB), but very special thanks are due to the University of Barcelona (UB) for allowing us to use many of its facilities. The Institut d'Estudis Catalans (Secció de Ciències i Tecnologia, Secció de Ciències Biològiques) provided us with funds and many services. The following institutions made their lecture halls available to us: the Biblioteca de Catalunya, the Reial Acadèmia de Ciències i Arts de Barcelona, the Reial Acadèmia de Farmàcia de Catalunya, the Reial Acadèmia de Medicina de Catalunya, and the Residència d'Investigadors-Consell Superior d'Investigacions Científiques. We obtained funds from the Generalitat de Catalunya and from the Spanish Ministerio de Ciencia e Innovación. We should also like to acknowledge Gas Natural Fenosa for its generous help. Some editorial companies sent their publications for exhibition during the Conference: Taylor & Francis, the Royal Society Publishing, and Birkhaüser-Springer Basel. A stand of the official journal of the ESHS, Centaurus, was also present.

However, we owe a special debt of gratitude to all the delegates without whose participation the Conference could not have taken place. There was an excellent response through papers and we are indebted to the many researchers and research groups that had chosen this conference to develop their activities. This justifies the existence of our societies, whose objective is to promote history of science, technology, and medicine.

The 4th Conference was devoted to the circulation of science and technology. Circulation is one of the most distinctive features of human activity, and continues to be a challenge for humanity. The study and analysis of the circulation of science and technology would result in a better understanding of the role of science and technology in our society. I should like to mention especially the papers presented as plenary lectures by Julio Samsó (Universitat de Barcelona),

---

[1] The previous conferences of the ESHS, which took place in Maastricht (2004), Krakow (2006), and Vienna (2008), offered excellent opportunities for the development of our discipline.

Efthymios Nicolaidis (National Hellenic Research Foundation, Greece), and Sona Strbanova (Academy of Sciences, Prague, Czech Republic). The excellent quality of their papers contributed to the success of the Conference.

As general coordinator of the Barcelona Conference, I should like to thank the programme committee for evaluating the proposals of sessions and of papers, and the local committee for taking care of the preparation and the development of the Conference. The present volume of Proceedings does not record exhaustively the development of the Barcelona Conference. Some participants informed us that their papers had already been selected for books or special issues of international journals. This may be verified by comparing the list of papers that appear in the general programme with recent publications in our field. In conclusion, it is a source of great satisfaction to have contributed in some way to the dynamic life of history of science, technology, and medicine.

SCIENCE AND THE EASTERN ORTHODOX CHURCH DURING THE 17TH-19TH CENTURIES

Efthymios NICOLAIDIS
National Hellenic Research Foundation, GREECE
efnicol@eie.gr;www.hpdst.gr

Preface

The following paper aims to give an overview of a "marginal" subject in the historiography of science: the relations science-Orthodox church during the period when new scientific ideas developed in Europe.[1] Indeed, the great majority of works on the history of the relations between science and religion follow the history of Western Christianity. This just follows the prevailing historiography about the Christian world. In his preface at *The Cambridge History of* Christianity, the Archbishop of Canterbury describes this prevailing historiography as follows: "the Church gradually builds up a centralized system of authority, filling the vacuum left by the fall of the Roman Empire; its ideological monopoly is challenged at the Reformation, and the map of the Christian world is reconfigured… Even in some good and sophisticated surveys of the world Christianity published in recent years, this remains the dominant picture. But Christianity is more various than this begins to suggest."[2]

The existing literature on science and religion contains virtually nothing that pertains to the vast part of Eastern Europe and Western Asia that constituted the Eastern Roman Empire, the Byzantine Empire. Contrary to Western Europe, here there was no political and institutional void; on the contrary, we observe an astonishing continuity, damaged but not abolished in 1204, date of the conquest of Constantinople during the Crusades. This continuity also involved the perpetuation of an educational system put in place at the end of Antiquity that was associated with both secular and ecclesiastical power, the latter placed under the authority of the former. In the sciences, this translated into the perpetuation of a tradition of teaching ancient Greek science in the Greek language, sometimes as reviewed and modified by the Greek Fathers of the School of Alexandria, such as Saint Basil. Hence conflicts –when they existed– were not "science versus Christianity", but rather ecclesiastical conflicts that traversed the whole society and consequently also concerned the sciences by always coming back to the question of the importance of secular knowledge and the possibility (or not) for humankind to conceive of Creation through science. For the medieval Oriental Empire, it was not a matter, as in the West, of rediscovering the Ancients, because they simply were always taught. During all this period, the Orthodox Church searched equilibrium between secular knowledge and revelation, hence between science and Christianity. The Hesychastic debate

[1] This overview is based on the book: E. Nicolaidis (transl. by S. Emanuel) *Science and Eastern Orthodoxy. From the Greek Fathers to the Age of Globalization*, Baltimore: Johns Hopkins U.P., 2011.

[2] Williams, Roman, Archbishop of Canterbury, "Foreword", Anglod, Michael, ed.*, The Cambridge History of Christianity.* Vol. 5, *Eastern Christianity*. Cambridge: Cambridge University Press, 2006 p. XVI.

(14th c.) that initially expressed the hostility of monks and lower clergy toward the secularization of the high clergy and especially its distance from the ascetic tradition, is an example. Hesychasts believed than man, through prayer and ascetics could have a vision of God and thus true knowledge comes from this effort and not from secular knowledge. But this belief did not mean that they totally rejected science. The ideological father of this movement, Gregory Palamas (1296-1359), in one of his religious texts posed the problem of the location of the centers of the spheres of the two elements, earth and water, and based himself on the science of Aristotle and the geometry of Euclid to answer the problem. In effect, the Hesychastic leader did not deny the utility of the sciences; he was more distrustful of the place granted to them by Byzantine power, seeing it as one of the causes of the secularization of high clergy.

After the conquest of Constantinople by Mehmed II the Conqueror who established the town as the capital of his vast Empire, the Byzantine tradition was kept by the Greek Patriarchates of Constantinople, Alexandria and Jerusalem. The Patriarch of Constantinople became the leader of the Orthodox communities of the Ottoman Empire, assuming the role of the control of education, hence of the relations between science and the Church. Indeed, after its definite victory on the Byzantine Empire, the Ottoman Empire based its domination on the organization of *millet*s, that is to say, a system for controlling non-Muslim populations that was in large part delegated to their religious leaders as appointed by the sultan. The first *millet* to be created was that of the Orthodox Christian Church, followed by the Armenian *millet* and the Jewish *millet*. The *millets* had their own laws (for example, when a member of a *millet* committed a crime, the law applicable was that of the *millet* of the person harmed, but when a Muslim was involved, *sharia* trumped everything). They collected their own taxes in compensation for their loyalty to the empire, and they managed their own educational system, which largely freed Orthodox communities from Islamic influences.

Mehmed II, subtle politician that he was, sought to alienate the Greeks from the Westerners, in order to reduce the chance of a crusade by Christian countries against the Turks. For this purpose he supported the enemies of the union of Orthodox and Catholic Churches. Mehmed, learning that the anti-unionist leader Scholarios had been made prisoner during the sack of Constantinople, liberated him and placed him at the head of the prime *millet* of the Ottoman empire and after raising him rapidly through all the ecclesiastical grades (he was not in a monastic order), he appointed him Patriarch on 6 January 1454.

Scholarios, in the spirit of “the Turks are better than the Latins”, maintained good relations with the Sultan and inaugurated the Ottoman period of the Orthodox Church. Having control over the Orthodox Christian *millet*, he tried to purge it of nefarious influences, whether Latin or Ancient Greek. Thus the first Patriarch of the Ottoman period took a rather uncommon decision for the Eastern Church: to burn publicly a book as Hellenizing, idolatrous and satanic. This was the *Book of Laws* of a late Byzantine scholar and astronomer, Pletho, who made an attempt to return to a pre-Christian religion.

This aversion towards the Catholic West in a period of a vivid revival of sciences in this part of the world, and towards the Ancient Greek tradition which was synonymous to secular knowledge and science, lead to the fact that the sciences did not figure among the preoccupations of the Orthodox Church of the Ottoman Empire. Indeed, for a century and a half after the Ottoman conquest, the patriarchate of Constantinople did not have a policy of teaching anything except what was useful for the renewal of the ecclesiastical hierarchy. The only organized Orthodox school in the Ottoman Empire was the patriarchal school of Constantinople, refounded in 1454. With regard to curriculum, it had nothing in common with its predecessor in the days of Byzantium, when mathematics and astronomy were taught at the highest level. And until the start of the 17th century, this was the sole organized school for the Orthodox population in the Ottoman Empire. The other schools for Orthodox pupils were to be found in Italy or in the Venetian possessions such as Crete.

The “Orthodox humanism” and science

Thus, after the Ottoman conquest, the Orthodox Church followed a reactionary policy towards secular knowledge and in particular science. The Byzantine renaissance of the 15th century which brought up the development of science ended abruptly. East Orthodox did not participate to the birth of the new European science of the 16th and early 17th centuries. Nevertheless due to the flourishing Greek Orthodox communities of Italy, the Orthodox world came quickly into contact with new European scientific ideas. The problem of the spread of new science to the East Orthodox world has thus been set.

This problem did not oppose clergy to secular scholars but the debates traversed the whole body of the Orthodox Church. In fact, the scholars of the orthodox world who propagated this new science were in large part ecclesiastics, sometimes occupying high positions in the Church hierarchy. It will be the rise of nationalities at the end of the eighteenth century and the effort of modernization of the nineteenth that will first forge in the Orthodox world the image of a man of science who is not linked to the Church.

As mentioned above, the leader of the Christian Orthodox *millet* was the patriarch of Constantinople. Thus the power of the Church with respect to education and science increased, compared to what it had had in the Byzantine era, when it shared this domain with the Byzantine emperor. As was the case since antiquity, the scholarly language of Orthodoxy was Greek, and so education was dispensed in Orthodox schools in Greek. Thus concerning science specifically, the policy adopted by the Church involved all orthodox peoples (whether or not they were native Greek speakers) of the vast Ottoman Empire, which at its apogee extended over three continents: Europe, Asia, and Africa.

A discussion on the validity of secular learning that expressed Italian humanist views had already taken place in the 16th century, among Greeks who were in contact with Italian culture.[3] But, as until the start of the 17th century, only a tiny number of Christian Orthodox thinkers –not more than fifty during the 16th century– were involved with the sciences this discussion remained marginal. The creation of a scientific community worthy of the name among Orthodox Christians of the Ottoman Empire would be a long and slow process; it would not be fully achieved until the century of the Enlightenment. Yet such a community began to make its presence felt in the17th century, with a movement that modern historians call "religious (orthodox) humanism."

Cyril Lucaris, the leading humanist in the Orthodox world, was born in 1572 in Crete, then under Venetian domination. He had been educated by a tutor in Heraklion and continued his studies in Venice and then at the University of Padua. In 1593, he found himself in Alexandria where his uncle, Meletios Pegas, was patriarch. He went into religious orders and was sent to Poland in 1594-1596, and then again in 1601-1602 to fight against the influence of the Catholic Church, which was converting Orthodox believers to Catholicism. During his stay in Poland, Lucaris realized the importance of Jesuit colleges, and analogously he organized the Orthodox Academy of Vilnius. At the death of his uncle in 1601, he became patriarch of Alexandria. In 1612, Lucaris was named throne steward of the patriarchate of Constantinople, and in 1620 he was appointed by the sultan patriarch of Constantinople. In a rare display of cooperation, Catholics and conservative Orthodox believers united to convince Sultan Murat IV to remove him in 1623. Restored and removed by the sultan no less than four times, Lucaris was finally strangled, on the orders of the Grand Vizier in 1638.[4]

Lucaris brought a small revolution to Orthodoxy, supporting the Protestant spirit in the midst of the Thirty Year's War. Lucaris was the prime source of Orthodox religious humanism, aiming to re-establish the teaching of letters and sciences, especially ancient Greek learning, among the Greeks of the Ottoman Empire. This was one of the reasons why his enemies accused him of preparing an insurrection of Greeks in the empire. With Lucaris's encouragement, his friend Theophilus Korydaleus (c. 1570-1646) applied the ideas of religious humanism to scientific teaching. Born in Athens, this scholar had followed the characteristic educational path of wealthy families of that era: primary education in his native town, then at the Greek College of Rome, and finally theology, philosophy and medicine at the University of Padua. There his professor of natural philosophy was Cesare Cremonini, the well-known Aristotelian adversary of Galileo.[5]

In 1622, in the reforming spirit in education (which in this context consisted of introducing into the curriculum something other than grammar and theology), Cyril Lucaris called upon Korydaleus to teach at the Patriarchal School of Constantinople, and a year later he became its director. Korydaleus introduced instruction in natural philosophy, geography, and astronomy. It was the first time since Byzantium that such education was dispensed at the very heart of the patriarchate of Constantinople. Obviously this innovation would not leave conservative circles of the Orthodox Church indifferent. The adversaries of his friend Lucaris accused Korydaleus of Calvinism, and his career experienced highs and lows, more or less following those of Lucaris's influence. In 1640, two years after Lucaris was assassinated, Korydaleus retired definitively to his native city Athens, to teach philosophy. His teaching of Aristotelian natural philosophy and logics would mark the whole Balkan Peninsula until the end of the 18th century.

The most novel features of Korydaleus's thought, were that, contrary to Orthodox scholars of the 16th century, philosophy served knowledge of both divine and profane things and that the happiness of man in his bodily consisted of studying. Not only did philosophy *not* depend on theology, but its methodology was valid for theological matters. This position inaugurated a new debate in the Orthodox world, which in certain circumstances would last until our own day.

This new ideology advocated by Korydaleus coincided with the birth of a scientific community in the Greek Orthodox world that might be called neo-Aristotelian. This nascent community was closely linked to the University of Padua, that favorite site of Greek university study. Some Greeks even made careers in Italy, as George Koressios "Lettore della Lingua Greca nello studio di Pisa", who wrote a dissertation in Italian against Galileo's mechanics of liquids or Ioannis Kotounios, who studied at the Greek College of Rome and at the university of Padua, and succeeded Cremonini in 1632 in the chair of Aristotle. But the great majority of them would teach Orthodox Greeks and write their books in Greek in order to spread scientific ideas in the Orthodox world.

It is very important to note that Korydaleus revival of the sciences, although influenced by Western Europe, had nothing to do with the "scientific revolution" that was simultaneously unfolding in Europe. Korydaleus, like all the Greek scholars influenced by religious humanism, sought ancient Greek science. He wanted to return to sources unrelated to the

[5] On Korydaleus see Tsourkas, Cléobule, *Les débuts de l'enseignement philosophique et de la libre pensée dans les Balkans. La vie et l'œuvre de Théophile Corydalée (1570-1646)*, Bucarest, 1948; 2nd ed., Thessaloniki: Institute for Balkan Studies, 1967.

Christian belief in the ancestral wisdom offered to humans by God. Like the scholars of late Byzantium, religious humanists argued that Orthodox believers were the natural heirs of Ancient Greek learning. Korydaleus studied Aristotelianism in Padua with Cesare Cremonini. Nevertheless, given the sentiment that Greeks were the legitimate heirs of Aristotle, the neo-Aristotelianism propagated by Korydaleus in the orthodox world was not that of his Italian professor, but a "direct line" Aristotelianism that drew on the tradition in the Greek language, starting with Alexander Aphrodisieus. In fact, Korydaleus was opposed to the theological interpretation of scholastic Aristotelians, insisting on the autonomy of philosophy from theology.

However, Korydaleus did have to respond to the questions that Christianity posed to Aristotelianism, essentially about the genesis of the world. For him the scholar's primary duty is to make a distinction between theology and philosophy, keeping the two intact and separate. This position is illustrated by the following short anonymous passage, written in 1669 at the latest: "What is true for theology is also true for philosophy, and what is false for philosophy is also so for theology. For theology is based on the light of faith, and philosophy on the light of nature."[6]

Thus natural philosophy is independent of theology, and so Korydaleus can allow himself to teach the former without any reference to the latter. He presents reasons for the utility of this physical science, which are both practical (for example, applications to agriculture), and theoretical, when it comes to the nature of the universe or of light. In the latter case, utility consists of the acquisition of wisdom, which is pleasing to God.

Speaking of the world, of matter, of genesis and decay, without presenting the Christian theory of nature as it had been formulated by the *hexaemerons* of the Church Fathers, was something new in the Orthodox world of the Ottoman Empire. Moreover, Korydaleus' written works were designed for education in the very orthodox Greek colleges. Korydaleus was not just anybody, he was close to the highest spheres of the Church during the reforming patriarchate of Lucaris, he had taught at the very heart of Orthodoxy, at the Patriarchal School. Given the stakes, the reaction in orthodox circles to Korydaleus' kind of teaching was rather moderate. And starting at the end of the 17th century, Korydaleus would be accepted as a great scholar by the orthodox world; his name became a reference in the domain of the sciences.

This rapprochement was facilitated by the thesis of the "double truth" (philosophical learning is independent of theology) he had advocated, even if his theologian contemporaries thought he expressed it in an extreme manner. Little by little, the hierarchy of the Orthodox Church came around to the idea of teaching ancient natural philosophy independently of the teaching of creation. This acceptance was prepared by the idea –increasingly widespread in the 17th century– that the Orthodox were the heirs of Greek splendor and learning. This idea was a comfort to the Orthodox of the Ottoman Empire, who felt subjugated to the Muslim state and at the same time threatened by the specter of Uniates, Orthodox believers who had converted to Catholicism. Without political power, wedged between Islam and Catholicism, the Orthodox Church sought support. And the Greek heritage was such a support, and Greek philosophy could therefore gradually assume its place in the education controlled by the Orthodox Church.

The first references to the new European scientific ideas

The introduction of a scientific curriculum in the Orthodox colleges did not bring any revolutionary scientific learning. But it did increase the interest in the education and it increased contacts with Italian scholarship. Between about 1630 and the end of the century, at least a dozen Greek colleges were founded or fundamentally renovated in the lands controlled by the Ottoman Empire. This education network would constitute the means by which the new science would later spread to Southeast Europe but this new science would not become central to the preoccupations of Greek scholars before the middle of the 18th century. Nevertheless, bits of this science were introduced at the second half of the 17th c. thanks to the circle of Greek Aristotelians. Alexander Mavrocordatos (1641-1709), a student at Padua who wrote his dissertation on the circulation of the blood, taught the new ideas of Harvey at the Patriarchal School between 1665 and 1672.[7] Nikolaos Koursoulas (1602-1652), in his commentary on Aristotle's *De coelo,* briefly presents the systems of Copernicus and Tycho accompanied by drawings. Ioannis Skylitzes (born in 1630) in his *Introduction to Cosmographical Sciences and Arts,* written before 1680, also presents the Copernican system but condemns it because it does not offer a greater simplicity in the explanation of phenomena.[8]

These few timid references to the ideas of the scientific revolution of the 17th century presented no danger whatever to the Orthodox Church. There was almost no reaction and certainly not a debate worthy of the name. The big majority of the clergy ignored all about the new system. The few scattered reactions such as this of Nektarios, Patriarch of Jerusalem

(1602-1676), were the exception. Responding to the accusations of the French Protestant Jean Claude (1619-1687) that the Greeks were illiterate and superstitious, Nektarios wrote that they did not need professors like Copernicus or Galileo since it was their fashion to overthrow sacred texts by sophistry.[9] But the debate did not go farther.

As already mentioned, until the 19th century there was little to distinguish between the positions of church and secular scholars. Debates and discussions traversed Orthodoxy itself: every tendency was present among the clergy. The first book to present the heliocentric system in detail was written by Michael Mitros, called "the geographer" (1661-1714), future metropolitan of Athens under the name Meletios. About 1690 Mitros wrote a huge manuscript in which he describes the Copernican system and presents all the new discoveries of Galileo which came in favor of it –sunspots, the moons of Jupiter, comets– and discusses the existence of heavenly spheres.[10] As a man of the Church, Mitros could not be a partisan of the Copernican system, but as a cultivated man, he realized that the new phenomena observed by Galileo could not be explained by the geocentric system. Therefore he followed the position adopted by the Jesuit astronomers and supported the geo-heliocentric system of Tycho Brahe which was in accordance with the new observations and with the Bible.

The main characteristic of the reforming orthodox current of 17th century is a "return to sources," but these sources are not the Church Fathers and ecclesiastical Byzantines, but the ancient sources of secular knowledge. After two centuries of uncontested Ottoman domination, the orthodox communities of the empire were becoming more powerful by controlling essential economic activities. This would give them the desire for an independence that would only become concrete after the middle of the 18th century, with the advent of new national ideas. These impulses toward independence assumed ideological expression, such as the affiliation of Orthodoxy with Greek culture in the form of religious humanism. Orthodox believers would thus feel strengthened in the face of both the Ottomans, who had the political power but whose science left much to be desired, having neglected their Arab scientific heritage, and the West, who were developing a new science that would put them at the forefront of world scientific and technological achievement.

This return to Hellenic sources, which in science was translated into the introduction of natural philosophy and mathematics into orthodox schools, had a major theological impact: relaunching discussion of the validity of science in relation to theology. But this renewed discussion took place in a new context. Now it was a matter of affirming the glorious past of a people who felt themselves "in decadence," subjugated by a non-Christian state. Until then the only reference of the Orthodox had been Byzantium. But now European humanism revalorized ancient Greece and offered a frame of reference that had been neglected after the victory of the anti-unionists.

A scientific Patriarch: Chrysanthos Notaras

In 1697, the Orthodox monk Chrysanthos Notaras was sent by his uncle Dositheos, Patriarch of Jerusalem, to Padua in order to complete his education. The curriculum of the University of Padua included theology courses that were also followed by Orthodox students. This might appear to contradict the hatred of Catholics felt by a majority of the Orthodox clergy, but the clerical aristocracy needed men who understood well the dogma of the "Latins" and a certain portion of the clerical aristocracy maintained good relations with the Catholic Church. Chrysanthos's professor at Padua was the Greek Catholic Nicolas Komninos. His attachment to Catholicism did not prevent him from considering Italy as a sinful land, and he maintained friendly relations with Dositheos, to whom he wrote that his nephew was leaving Padua more knowledgeable but without having been perverted by Italian morals. In this period the teaching at the faculty of arts was Aristotelian. A curious mind that knew that a new science had existed for a long time, Chrysanthos was not going to be content with Aristotelian study. In 1700, at the end of his study in Padua, he went to France, another sinful land according to the Komninos.[11]

In Paris, Chrysanthos made the acquaintance of liberal theologians such as Louis Ellies Du Pin, Alexandre Noël, and Michel Le Quien. Still more important for him was his contact with men of science He asked to visit the Paris Observatory, and he was welcomed and lodged there for a week by John Dominique Cassini, first director of this modern establishment. As he himself wrote, "there we observed with him [Cassini] with the aid of the largest telescopes the Moon, Jupiter and its so-called satellite-stars, the galaxy and other things. He then told us that by using several methods and observations, he discovered that one minute of the earth's circumference –that is to say, an Italian Mile– is five thousand, seven hundred and six feet of Paris, or five thousand eight hundred and eighteen geometric feet."[12] Apart from astronomy, Chrysanthos expressed interest in methods of measuring the earth, that is, in surveying and the determination of coordinates and had the

[11] On Chrysanthos see Stathi, Pinelopi, *Χρύσανθος Νοταράς, Πατριάρχης Ιεροσολύμων, πρόδρομος του Νεοελληνικού Διαφωτισμού* [Chrysanthos Notaras, Patriarch of Jerusalem, precursor of the Greek Enlightenment], Athens: Syndesmos ton en Athinais Megaloscholiton, 1999.

[12] Chrysanthos Notaras, *Εισαγωγή εις τα γεωγραφικά και σφαιρικά* [Introduction to geography and the sphere], Paris, 1716, p. 92.

occasion to learn about Jean Picard's work, which was the state-of-the-art science on these subjects. He even constructed a sort of astrolabe according to Cassini's instructions and had engraved on it the following inscription: "This instrument has been fabricated by the monk Chrysanthos according to instructions from Cassini for his brothers in Jerusalem, so that they may adore God through his works." [13]

To adore God by science, that means understand the Creation by secular knowledge, and was not a new idea for the Orthodox; we have encountered it several times during the Byzantine period and was promoted by Korydaleus. What is new is that Chrysanthos, who on the death of his uncle Dositheos (1707) became Patriarch of Jerusalem, departed from the scientific tradition of Orthodox humanism that accepted only Hellenic science as valid. As a precursor of the Enlightenment he was able to present to the Orthodox world, with his immense moral authority, the new European scientific ideas.

Returning from Paris, Chrysanthos wrote a book that reflected what he saw and learned in this capital of science, the *Introduction to geography and to the sphere.* This was the first printed book to present the new science to the Greek world. Because of his position as patriarch, the prudent Chrysanthos presented this new science in such a way as not to raise theological problems. In the astronomical part, he presented the Copernican system while prudently explaining that for practical astronomy (determination of the positions of heavenly bodies) both systems −heliocentric and geocentric− were valid. Why then, he concluded, not lean to the latter as closer to Scripture? Just as cautiously, he publicized the heliocentric system through the engravings in his book and not in the text. Out of nine engravings presenting the subject, only one offers the "system of the world according to Ptolemy", one according to Tycho Brahe, and other seven the heliocentric system in detail, of which two are the "system of the world according to René Descartes", which includes the Cartesian whirlpools explaining the functioning of the world.

The presentation of the heliocentric system was totally symbolic in Chrysanthos' book. Although an able mathematician himself, he did not present any mathematical aspect of the Copernican system, remaining at the level of qualitative description. Chrysanthos choose a domain other than astronomy, that of geodesy, to present the new learning in more detail. In geodesy, Chrysanthos, aware of Picard's work, presented the rigorous surveying methods, as well as the instruments of triangulation and gave details of their fabrication. He would make his own measurements and tried to re-determine the coordinates of various cities in the Balkan Peninsula.

The very Orthodox Patriarch Chrysanthos considered "Latin" science the flower of civilization: "It was a common saying among the Greeks that what was not Hellenic was barbarous. In those days the barbarian nations were Germany, France, Holland, and others. But when they had received Hellenic wisdom, when they had established academies, gymnasia, and other schools, it was the barbarians who became Hellenes and the Hellenes became barbarians by losing all these things".[14] His project was to create schools in the Orthodox world. He believed that princes should contribute financially to the foundation of what would be the "best of the commonwealth," for in spending for this purpose "sacred revenues do not diminish but increase; whereas once they nourished laziness and do-nothings, now they are being encouraged to nourish and sustain wisdom, knowledge of God, the sciences, and all psychic and physical needs."

A condemnation of the new philosophy by the Church

Methodius Anthrakites (circa 1660 – circa 1736) has as a common Greek student, studied in Padua. He was author of an enormous textbook in three volumes, the *Mathematics Course,* which would shape mathematical education in the Greek Orthodox world during the first half of the 18th century.[15] This book provides a complete course, detailed and rigorous, of the "mathematical sciences" as they were taught in Padua at the start of the 18th century, plus some Byzantine texts.

Therefore, there was nothing revolutionary in the Aristotelian teaching of this monk. However, Anthrakites seems also to have taught –or at least presented– the philosophical ideas of the French philosophers Nicolas Malebranche and René Descartes. No doubt this novelty, and the fact that he clearly stressed the teaching of science and not philological subjects, led Orthodox fundamentalists to accuse him before the Holy Synod of being a heretic. In 1723 he was summoned to Constantinople to refute these accusations. Condemned, he was excommunicated and his educational books banned. After confessing his Orthodox faith and ceremoniously burning some of his own manuscripts, the Church lifted his excommunication and authorized him to teach again, on condition that he followed the course of Korydaleus. In his novel defense, Anthrakites claimed that the Church was condemning him for his philosophical ideas and not for having departed from Orthodox dogma. Thus he re-opened the debate within the Church on the separation between philosophy and theology. His stance succeeded only in sharpening the anger of the Holy Synod, which reaffirmed its position that only the Peripatetic

15 Anthrakites, Metodius, *Οδός μαθηματικής*, Venice, 1749; second edition 1775.

philosophy of Aristotle should be taught.[16] This controversy bore on the principle and not on the subjects actually taught in natural philosophy. In fact, Anthrakites always remained an Aristotelian, and into the 18th century he perpetuated the Orthodox humanist ideas of the previous century, which featured the renaissance of Greek science.

Clerics promoting new science during the Greek Enlightenmen

The introduction of new science in the Orthodox world follows the teaching of this science at the University of Padua. Indeed, this university was the main destination for Orthodox students until the middle 18th century, because the Greek community of Venice was until then the most important Greek community in the Western Europe. There, it was not until 1739 that this new physics was fully taught by the chair of *ad mathesim et ad philosophiam experimentalem*, (mathematics and experimental philosophy) occupied by Giovanni Poleni (1683-1761), who created his famous *Teatro di filosofia sperimentale* (theater of experimental philosophy), equipped with 400 instruments to teach experimental physics. The first reactions by Orthodox students to these reforms were negative. If they went to Italy, it was usually to study Greek sciences, which were taught at a rather elementary level in the Greek schools of the Ottoman Empire. But gradually a new discourse arose that aimed to reconcile the existence of the new science with the idea of a renaissance of ancient Greek science. This new discourse appeared in the prologues of Greek science books around the middle of the century, some fifteen years after the establishment of the chair of experimental physics in Padua. Until that time, Greek scholars conceived of science as solely about Greek and early Byzantine science. Henceforth, the new European science would be integrated as the brilliant heir of ancient science.

Eugenios Voulgaris (1716-1806), the most influential Greek scholar and cleric in Southeastern Europe in the second half of the 18th century, was born in Corfu, a Venetian dominion. He studied at Padua, where he followed the first courses in experimental physics from Poleni, and in 1742 became director of a School in Jannina. There he taught Leibniz, Locke, and Voltaire, which exasperated the Aristotelians who forced him to go teach these insanities elsewhere. In 1753, the enlightened patriarch Cyril V created a school on Mount Athos and appointed him to direct it. At the heart of mystical Orthodoxy, then, Voulgaris taught, according to the terminology of the scholars of his time, the new science and the new philosophy, that means the ideas of the European "scientific revolution" developed after the 16th century. This innovative teaching drew him many students as well as many troubles, which obliged him to quit the Academy in 1758. In 1759, he was called upon to head the Patriarchal School in Constantinople by Seraphim II, a patriarch who supported the Greek revolt against the Turks provoked by Russia; Seraphim also tried to establish innovative education in the capital of Orthodoxy. The experiment lasted two years, until Seraphim's fall. The new patriarch and the majority of bishops were hostile to this intrusion of Western civilization into Orthodoxy. Voulgaris would leave again, and after a stay in Romania (then administered by Greek princes named by the sultan), he arrived in Leipzig with the goal of publishing teaching manuals like his *Elements of mathematics,* based on a book by Andreas Segner. There he met the Russian Marshal Theodore Orlov who introduced him to Catherine the Great. Voulgaris, disappointed at résistance to new ideas, and the intrigues in the circles around the patriarchate of Constantinople, finally settled in Russia, where he was named archbishop of Slavonia and Chersonesos. He had been named in 1776 a member emeritus of the Science Academy of St. Petersburg.[17]

Voulgaris is as good example of the relations between enlightened Orthodox clerics and the Enlightenment. On the one hand, he considered himself as heir of the Ancient Greeks and was proud of it; on the other hand, he thought that the Greece of his day –confused with the *millet* of the Ottoman Empire– was totally decadent and would owe its salvation to the teaching of the new European science. For him, the new science consisted of the development of the science of the Ancients. "[Diophantus] is considered the sovereign of all arithmetical thinking. But his marvelous invention, the art called algebra, was developed and perfected by François Viète, René Descartes, and others," he wrote in his prologue to Tacquet's *Elements of geometry*.[18] This idea would be developed by other Greek partisans of the Enlightenment who considered the great European savants as the children of the ancient Greek savants.

Voulgaris' books were soon eclipsed by those of his junior Nikephoros Theotokis (1731-1800), who followed a similar career. Also born in Corfu, he, too, had studied experimental physics with Poleni and then mathematical sciences with Eustachio Zannoti, director of the Bologna Observatory. After his studies in Italy, he returned to Corfu, took his monastic vows, and created a school where the new science was taught. In the 1760s he was called by the patriarch to Constantinople where he was appointed Preacher of the Grand Church. His teaching of the new science and philosophy shocked conservative circles of the Church and Phanar; so Theotokis went to Jassy in Romania, where the ambiance

[18] Voulgaris, Eugenios, *A. Τακουετίου, Στοιχεία Γεωμετρίας*, Vienna, 1805, p. XI-XII.

seemed more liberal than in the capital of the Ottoman Empire. He soon left for Leipzig, where (like Voulgaris) he went to publish his manual *Elements of physics*.[19] In 1773 he returned to Romania, where he directed the Academy of Jassy. Facing résistance to his teaching, and considered a revolutionary by both clerical and secular conservatives, in 1776 he accepted an invitation from Voulgaris to join him in Russia, where three years later he succeeded him as archbishop of Slavonia and Chersonesos. In 1782 he became archbishop of Astrakhan and Stavropol.[20]

Theotokis' *Elements of physics* became the book of reference for the diffusion of new science in the Orthodox world for at least two reasons. The book was not content with presenting "novelties"; it taught physics in a rigorous manner that required solid mathematical notions that would be supplied in another manual by Theotokis, the *Elements of Mathematics Compiled from the Ancients and the Moderns*. Thanks to this manual and the one on mathematics, Theotokis was the first to present differential calculus to Greek schools in a rigorously didactic way. The *Elements of Mathematics* devoted eighty pages to it, using Leibnitz's terminology.

The late reaction of the patriarchate against science

Adherence to the new sciences, which were accompanied by the philosophical and political ideas carried by the Enlightenment, was strongly shaken by the French Revolution, when a portion of the clergy as well as conservative circles of the Phanar (the Constantinople's quarter of Greek aristocracy) close to the Sublime Porte, feared republican impact on Greek partisans of the Enlightenment and atheistic fallout from the Revolution. As in Russia, even enlightened people in favor of new ideas made retractions. In 1805, almost ninety-year-old Voulgaris, then in Russia, gave his accord for the publication of his old manuscripts, a translation he had done almost fifty years earlier of the fourth part (titled "De systemate Universi") of a book by Fortunatus a Brixia (1701-1754), *Philosophia sensiuum mechanica methodice tractata*, originally published in 1747. This book presented cosmological systems from Plato to Newton, via the Church Fathers, Kepler, Gassendi, Descartes, etc., and it took the part of the Tychonian system that saved phenomena while remaining faithful to sacred texts.

The reaction of the supreme leader of the Orthodox *millet*, the patriarch of Constantinople, against the diffusion of new science culminated before the unleashing of the Greek national revolution and was triggered by the wind of revolt that blew through the Balkans after the Serbian uprising. At the same time, Orthodox reaction was favored by the counterrevolutionary ambiance created by the Holy Alliance of European powers, as well as by the weakening, after the Napoleonic wars, of the merchant caste, which had been the principal pillar of support for innovative scholars. This time around, reactionary forces were able to impose their will. Between 1819 and 1821, the principal Greek schools of the Ottoman Empire (in which the new program was taught) were either closed or had to change their orientation. The subject most affected by these measures was science.

The more the head of the Church hardened his position, the more aggressive the partisans of Enlightenment became. Nicolas Piccolo (1792-1865), a philosopher and physician of Bulgarian origin, published in 1820 a poem, barely allegorical, against the obscurantism of the Church, superstitions, and ignorance, and in favor of Western education. Piccolo denounced the "disgusting mob" that was tearing Greece apart, and despaired that a "band of monsters" had thrown itself on Smyrna (an allusion to the closing of the School of Smyrna by reactionary forces led by the Church). This diatribe provoked an immediate attack from the patriarchate of Constantinople, represented by the hegoumenos Ilariôn, the abbot responsible for educational matters and for the new Greek printing press of Constantinople. Ilariôn imposed censorship not only on what was published by the Greek printer, but on all books sold in Constantinople.[21]

The Church's opposition to teaching the new science took an institutional form with a patriarchal encyclical written in March 1821 that dealt with education:

> Everywhere there reigns a disdain for matters of grammar, and the arts of logic and rhetoric and the teaching of the elevated theology are completely ignored. This disdain and ignorance come from the exclusive love of students and professors for mathematics and science, and a cooling off for our faith […] For the Nation, the teaching of grammatical classes is more beneficial and necessary than mathematical or scientific classes […] for what is the advantage for the students who follow these courses to learn figures and algebra, cubes and cubocubes, and triangles and trigonosquares, and logarithms, and symbolic calculations, and projected ellipses, and atoms and voids and whirlpools,

> and forces and attractions and weight, and qualities of light, and polar auroras, and optics, and acoustics, and thousands of similar and monstrous things, in order to count the sand on the shore and the drops of dew and move the earth if support is offered via Archimedes, yet they are barbarous in their speech and poor in their writing, ignorant in their religion, perverse and corrupt, noxious to politics, these obscure patriots, unworthy of the hereditary call.[22]

It was not rare in these tumultuous years for scholars to be denounced by the Church to the Turkish authorities as revolutionaries advocating the overthrow of the sultan. The patriarch Gregory V and the metropolitan of Chios, Plato, used this tactic against the director of the Chios Gymnasium Neophyte Vamvas, as did the metropolitan of Smyrna against Constantine Economos, director of the Smyrna Gymnasium. The struggle against science reached its paroxysm in March 1821 when the Holy Synod was convened in Constantinople in order to put a stop to "philosophical" classes. The exact date was March 23rd, and already Christians would be arrested and executed after the rebellion of Prince Ypsilanti in Romania, but the news of the Greek national uprising in Peloponnese had not yet reached the capital. Shortly afterward, on April 10th, the same Gregory V who condemned scholars as subversive elements would himself be hanged, on the order of the sultan, because he had not been able to contain the rebellion. The victory of this rebellion seven years later will dramatically change the geography of the Orthodoxy by dismantling the unifying orthodox *millet* in several independent states, with their own Orthodox Church and educational and scientific culture. These States, seeking for modernity, will found new educational structures comparable with those of Western Europe. Science will then be taught in a standard curriculum, following this of secondary and university level European education. From then on, science-religion debates will be comparable with those of Western Europe, and will focus on Darwin's ideas and materialism.

THE DIFFERENT HISTORIOGRAPHIES OF SCIENCE. THEIR ADVANTAGES AND SHORTCOMINGS

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 27.

THE DIFFERENT STRATEGIES IN HISTORIOGRAPHY OF SCIENCE. TENSIONS BETWEEN PROFESSIONAL RESEARCH AND POSTMODERN IGNORANCE

Michał KOKOWSKI

michal.kokowski@gmail.com

Abstract

History of science, as a branch of knowledge, is a discipline of two countenances. On the one hand, as a kind of history, it is one of the humanistic disciplines. As this type of discipline it interacts with other humanistic disciplines, such as general history, methodology of history, philosophy (including epistemology, methodology, rhetorics, etc.), sociology, theory of literature, theory of cognition, etc. Moreover, history of science is one of the branches of knowledge called science studies or science of science, which also include philosophy of science (with epistemology, methodology, rhetorics, ontology, ethics, theory of values), sociology of scientific knowledge, and politics of science. Hence, history of science develops in strict relationships with the branches mentioned.
On the other hand, as a kind of reflection on science, history of science interacts with science itself (or more precisely, with particular sciences themselves).
Such a dual nature of history of science lays the groundwork for various approaches to this branch of knowledge, different methods of researching history of science and writing about it, based on different combinations of the so-called internal and external factors of science development. As a consequence, we observe the existence of a wide spectrum of different interpretations of the history of science. The mentioned spectrum extends from a detailed, professional case study approach, to the ignorant postmodern approach.
In this paper I would like to develop the issues sketched.

Let us introduce two terms at the very beginning: “the historiography of science” and “ a historiography of science”.

By the term “the historiography of science” I mean “the study of the way history has been and is [(added by M.K.:) analysed and] written — the history of historical writing” (Furay, Salevouris (1988) p. 223).

From the history of this branch of knowledge we know that there were and there are many different approaches to study the history of science. In consequence, we can show *many distinct historiographies of science*, that is, different ways, styles of studying and writing on the history of science.

Thus, we may conclude that *the historiography of science* is composed, among others, of *distinct, different historiographies of science*. Let us list them explicitly:

1. historiography of science analysed and written from the point of view of positivistic philosophy, that is positivistic historiography of science, which we may define as Montuclian, Whewellian, Tannerian, Machian, Sartonian, Duhemian, Conantian, Crombian, Neugebauerian, ...,
2. historiography of science analysed and written from the point of view of history of ideas, which we may define as Lovejoyan, Koyrian, ...,
3. historiography of science analysed and written from the point of view of contemporary philosophy of science, which we may define as Fleckian, Bachelardian, Popperian, Kuhnian, Lakatosian, Feyerabendian, Hackingian (historical epistemology), ...
4. external, social, sociological or socio-political historiography of science, which we may define as Marxian (Hessen's, Bernal's), Bloorian – Barnesian – Shapinian (*The Strong Programme in Sociology of Scientific Knowledge*), Collinian (*The Empirical Programme of Relativism*), Latourian – Woolgarian – Knorr-Cettinanian (*Ethno-methodological Approach*), Callonian – Latourian (*Actor-Network Theory*),
5. historiography of science analysed and written from the point of view of cultural studies of science), that is, cultural historiography of science or socio-cultural historiography of science (Dear (1995),
6. postmodernist historiography of science (propagated by "Postmodernists", but severely criticised by the "Friends of science" in the 1990s quarrel of the so-called "Science wars") – see: Sokal, Bricmont (1997), Sokal (2007),
7. rhetorical historiography of science, which we may define as Prellian, Grossian, Dearian, Woolgarian, and Mossian – see: Haris (ed.) (1997), Fahnestock (2008),

Then, using terminology assumed by Russell (1984), Harrison (1987) and Hughes (1997), among the above mentioned kinds of historiographies of science, we may differentiate between two groups:

1. *Whig historiographies of science*
2. and *prig historiographies of science*.

Or, using the terminology assumed by Brush (2007):

1. *Modernist historiographies of science*
2. and *contextual historiographies of science.*

Furthermore, it is also worth applying in this context the terminology applied by Daston (1989), Hacking (1992), (2002), Sturm, Feest (2008), Daston, Peter Galison (2007), Kusch (2009), Pisano, Gaudielo (2009), in their analyses of historical epistemology and to distinguish three kinds of historiography of science:

1. The objective historiography of science (recorded in text-books as a list of data along with the corresponding mathematical laws, and taught through its techniques and objective concepts).
2. The subjective historiography of science (that is, the history of thoughts and experiences of scientists).
3. The effective historiography of science (that is, historiography (a) of epistemic concepts, (b) of the objects of scientific inquiry, and (c) of the dynamics of scientific developments, as they can be extracted from an analysis of scientific texts or practices).

Then, irrespective of the differences between distinct historiographies of science, we can show a simple schema for all such historiographies. Namely, every historiography of science is always written from a specific point of view determined by a certain choice of a set of more or less clear assumptions, concepts and ideas. Let us call this point of view, *the interpretative core* of a historiography of science.[1]

We can explain what the role of the *interpretative core* of a historiography of science is using the following comparison taken from the theory and practice of photography, spectroscopy and spectrometry. Namely, the interpretative

[1] I go in this point on footnotes of several scholars such as Józef Tischner, Imre Lakatos, and Gerald Holton. See Kokowski [1997].

core is a kind of a colour filter that transmits a certain limited range of frequency of light. Hence, like a photograph can take different photos of the same objects using different colour filters, we can provide different pictures of the history of science using different *interpretative cores*, that is, using *the different historiographies of science*.

The interpretative core a historiography of science is composed of two strata:

- the purely declarative stratum (it is based on rational argumentations)
- and the non-declarative stratum of a specific climate of thoughts, ethos, spirit or vision (it permeates and supplements the argumentation).

Let us note that the diversity of historiographies of science is caused by two reasons:

- In each historical epoch, there is a variety of possibilities of writing on history of science. This variety of possibilities is caused by the fact that we want to analyse the different combinations of internal and external factors of development in science. To achieve this task, we need to pick out concepts, ideas, etc., stemming from, among others, related branches of history of science, such as philosophy of science, sociology of scientific knowledge, etc. In other words, we can choose different possible interpretative cores.
- Science itself changes its meaning along history (this is reflected, among others, in the different classification of science from ancient times to nowadays).

Furthermore, the interpretative core of each historiography of science is always determined by a certain understanding of science assumed by its authors. Namely, it expresses the answers for such fundamental questions as follows:

- What is science?
- Whether does science differ in something from other branches of culture or not?
- Whether can one identify science with its results only?
- Whether can one identify science with methods and results?
- Whether can one identify science with a certain social institution?
- Whether can one identify science with a certain kind of argumentation and rhetoric?

Hence, each interpreter of the history of science always assumes more or less consciously a certain philosophy of science and ... a certain sociology of scientific knowledge.

Let us notice that according to the statement of Imre Lakatos:

> "Philosophy of science without history of science is empty; history of science without philosophy of science is blind" (Lakatos (1971), p. 91).[2]

Then, according to a degree of the granularity or the level of detail of the interpretative core, we can say on:

- macro-historiographies of science (when we are able to describe science in general aspects)
- and micro-historiographies of science (when we are able to describe science in details).

To better understand the problem of variety of historiographies of science, I postulate to introduce another term – "The Perfect Historiography of Science". It is an abstract, ideal notion. "The Perfect Historiography of Science" is written by a perfect subject that has a perfect, absolute knowledge on the history of science. (In the margin, let us notice, that this subject may be called "God").

However, we all know people, not being perfect beings, have limited cognition of the world. This simple remark regards also to the results of our ways of interpretation of the history of science. Hence, we always create limited models of the history of science. In other words, every historiography of science is always only one of many possible cuts of *The*

---

[2] Lakatos Imre (1971) *History of Science and Its Rational Reconstructions*, [in:] P. S. A. 1970 , R. C. Buck, R. S. Cohen (red.), Reidel, p. 91-135.

Perfect Historiography of Science. We can illustrate it, by saying that *The Perfect Historiography of Science* can be represented by a sphere, and *a certain historiography of science* – by a circle, one of its cuts.

In this context, the fundamental questions arise:

- Whether are we allowed everything (Fayerabend's "anything goes") in making our historiographies of science?
- Whether are we entirely free in creating the interpretative core of a historiography of science?
- Whether all possible interpretations are equally good?

I have the same answer for these three questions – "Unequivocally No!".

My further *thesis is: Every historiography of science has its advantages and shortcomings.* The great diversity of approaches to the study of the history of science brings about both positive and negative consequences to research in this branch of knowledge – both profits and losses, so to speak. On the one hand, plurality of attitudes can create new promising perspectives in research, if, for example, such approaches are complementary to each other. On the other hand, however, it can be very destructive to research, because it allows for instances of relativism, overspecialization, or for ignorance by authors and propagators of falsely based assumptions (that, nevertheless, have great influence on the broad public).

One problem noticed Edward Harrison in his article *Whigs, prigs and historians of science*, published in "Nature" vol. 329, p. 213–214 (17 September 1987).

> "The whig interpretation of the history of science, practised by most scientists according to historians, commits the crime of reconstructing past science in the context of today's science. The prig interpretation, practised by many historians, adopts a superior attitude to historical work by scientist, and from fear of being unhistorical commits what it supposes to be the lesser crime of being unscientific" (quoted from Hughes [1997] p. 21).
>
> "By communicating the history of science only to historians, and deigning not to communicate it to scientists, the historian lives neither in the past nor the present, in a never-never land where ignorance is bliss, unable to evaluate (and necessary to discount) the effect of modern science on modern styles of thought" (quoted from Hughes [1997] p. 22).

In contrast to Harrison (1987), I would like to emphasize that the problem mentioned is much more complicated.

1. We can cultivate the history of science in two fundamental different ways. On the one hand, the history of a particular branch of knowledge can be researched as a part of this branch of knowledge. For example, the history of physics can be researched as a part physics. On the other hand, the history of a particular branch of knowledge can be researched as a part of general history. These are two distinct research perspectives that show different pictures of science.
   In the margin, it is worth noticing that Sarton's problem of two cultures –Snow (that is, the culture of Science and the culture of Humanities), and Sarton's third culture –Snow (that is New Humanism) manifest here.
2. The historian of science has every right to write on the history of science in a different manner than the scientist, if the former writes on science in which held true the other classification of science than modern one's.
3. Writing on the history of science, the interpreter (either scientist or historian of science, philosopher of science, sociologist of scientific knowledge, ...) are not allowed to be an ignorant in this branch of knowledge and related branches of knowledge.

Furthermore, we can classify all works on history of science according to the following schema. There are:

- very weak works (treating the subject on a very low level of competence; such works have often a great "impact factor"[3]),
- mediocre works (treating the subject on a weak level of competence – the phase of "normal science"),
- ordinary works (treating the subject in a normal level of competence – the phase of "normal science"),

[3] Nevertheless, I am very skeptical in regards to the application of the idea of "impact factor" and its use to evaluate the real importance and quality of these works. I agree in this point with the stance of the scientific editors, presented in two texts: The European Association of Science Editors (2008) and Andersen (*et al.*) (2009).

- mature works (developing the accepted axioms and treating the subject in a very competitive way),
- premature works (treating the subject in a fresh way, however with insufficient justification of the proclaimed theses),
- innovative works with a low "impact factor" (treating the subject in a very fresh and exciting way, however without a greater impact),
- innovative works with a high "impact factor" (treating the subject in a very fresh and exciting way, with a greater impact – the phase of "revolutionary science").

Then, on the hand, it is easy to show many examples of great competence in the field of history of science.

Among the mature works, we can mention, for example, the works of Jean-Étienne Montuc – – влович Юшкевич (1906–1993) on history of mathematics, the works of Alistair Cameron Crombie (1915–1996) on history of science, etc. Let us notice that these works represent the positivistic historiography of science.

Among the innovative works with a low Impact Factor, we can mention, for example, The *Genesis and Development of a Scientific Fact* by Ludwik Fleck published in 1935, that became popular among philosophers only when *The Structure of Scientific Revolution* by Thomas S. Kuhn was published in 1962.

The latter mentioned work is a good example of the innovative works with a high Impact Factor.

On the other hand, unfortunately, it is not difficult to show many examples of real ignorance in the field of history of science. And both scientists and historians of science, philosophers of science, sociologists of scientific knowledge, etc. are the authors of such wrong works. I give here only two extreme examples.

- The most common mistake proclaimed by scientists is the anachronistic myth that mature exact sciences were born only in modern times.
- One of many important errors made by humanists (mainly experts of literature theory) in the interpretation of the history of science is the creation of the so-called postmodernist historiography of science.

EPISTEMOLOGICAL ASPECTS OF HISTORIOGRAPHY OF SCIENCE IN GREECE

Constantine D. SKORDOULIS
University of Athens, GREECE
kostas4skordoulis@gmail.com

Abstract

This paper examines the epistemological aspects of the course of development of the discipline of history of science in Greece focusing on three controversial themes: i) "Continuity" with the ancients, ii) reception of modern science in the Greek speaking communities in the 18th- early 19th centuries and finally iii) the issue of teaching the history of science in the science classroom.
Starting with the work of the first Professor of history of science, Michael Stefanidis, this paper examines the transition from a discipline of history of science dominated by the attempt to establish the continuity of Greek Science from the ancients onwards up to the last decades of the 20th century when a new generation of historians of science, which appears on the scene in the late 1970s, prevailed in the cultural life of Greece.
This new generation considered the argument for "continuity" as an ideological construction, and turned its attention in the study of the post-Byzantine era, in a period that has been called "Neo-Hellenic Enlightenment", and focused on the study of reception and assimilation of the ideas of the 17th century scientific revolution in Greek speaking communities.
Finally, this work examines the newly established relations between the historians of science and the historians of science education considering the study of the two fields tightly connected in the Greek framework and discusses the epistemological problems arisen from proposals and attempts to incorporate history of science in the teaching of science in line with the developments in the international community.

Michael Stephanides, the epigones and the issue of "continuity"

Michael Stephanides (1868-1957) is considered by many to be the first Greek historian of science. Stephanides studied philology and science at the Faculty of Philosophy of the University of Athens. The science chair at that time belonged to the Faculty of Philosophy. This unusual combination in this epoch ascribed to him the nickname "physico-philologist" by his fellow students. Being a scientist, philologist and historian, he had the ideal profile for addressing the emerging field that history of science was at that time.

Stephanides in 1896, earned his living as director of the Ottoman "Chemistry Civil Service of the Aegean Sea"[1] and at the same time he was professor of physics and history at the Gymnasium of Mytilene (the capital of the island of Lesbos).

During his service in secondary education, he published the *Mineralogy of Théophraste*, in which he compares the old and modern taxonomies of chemical elements. This is the first Greek book of professional history of science escaping the encyclopedic approach of previous works, written mostly by scholars trying to present developments in their field as scientific. *Mineralogy* is also the first Greek book of History of Science with an impact in the international community of history of science. In the following period of his life, Stephanides pursued a research career. After writing an article (1904) about Benjamin of Lesbos, his compatriot scholar of the 18th-19th century, he devoted himself to the study of Alchemy, publishing in 1909 his most famous scientific work: *The Art of Psammurgique and Chemistry*. In this book, he studied "psammurgique" vis-à-vis the Arab alchemy and Western "χρυσοποιι′α" (gold making) arguing that the Greek, Alexandrian and Byzantine alchemical schools are very distinct from the corresponding Arab and Western.

Stephanides was deeply influenced by the historiographical ideology of the modern Greek State, which advocated the "continuity" of Greek history and consequently continuity of science from antiquity to the 19th century, distinguishing three historical stages: ancient Greece, Byzantium and Modern Greece (which begins in 1453). Under this scheme, Stephanides published several studies on the history of Sciences in Byzantium and also at the time of Ottoman rule. Stephanides promoted a schema of continuity of the Byzantine sciences with the Hellenistic Alexandrian heritage. He was also the first to claim that during the period of Greece under Ottoman rule there was continuity in science education, which reinforces his thesis of continuity of ancient Greece until the late 19th century. This thesis, which implies that the modern Greeks are heirs of "Hellas" has been deeply influenced by the national state ideology and has been used extensively by state intellectuals to render the newly born modern Greek state a cultural coherence.

In every article Stephanides was writing, he tried to demonstrate the contribution of Ancient Greeks and Byzantines in all the areas it addresses. Nevertheless, his works are of value because they study a field largely unexplored: the sciences in Byzantium.

Chronologically, Stephanides is placed between Paul Tannery and Joseph Mogenet, the first having studied the field of mathematics in Byzantium, the second that of astronomy, while Stephanides has mostly dealt with that of alchemy (Nicolaidis 2010).

In 1924, while he was assistant professor of history at the University of Athens, he was successful in founding a chair of history of science at the Faculty of Science, which he held until his retirement in 1939. This is one of the first chairs of history Science in the world academia. Two factors played a significant role for the foundation of this Chair: i) the importance of the antiquity (including Hellenic science) for the formation and the constitution of the ideological apparatuses of the Greek state and ii) the personality of Stephanides himself, who was recognized as a prominent member of the international community of history of science. Indeed, he maintained a correspondence with George Sarton who encouraged him in his research on the sciences in Byzantium. He also was a member of the International Academy of History of Science publishing widely in various international journals and participating in international conferences. It has to be noted at this point that Stephanides was present in the Second International Conference of History of Science in London in 1931. This Conference acquired importance due to the presence of the Soviet delegation under Bukharin and the subsequent initiation of the field of Social History of Science. This remained largely unnoticed by Stephanides who wrote in his report that the Soviet papers given in the conference were not all related to history of science and makes no reference at all to the paper by Boris Hessen.

Stephanides was elected member of the Academy of Athens in 1938. In the same year, he published his textbook *Introduction to the History of the Sciences* which is a tribute to ancient Greek Science. Indeed, 240 of the 290-pages of the book are devoted to Greek and Byzantine Science and moreover, he argues that the method of the Ancients do not differ to that of the science of his time.

The personal success of Stephanides did not have any benefit for the scientific community of Greece. We do not see at this time the birth of a community of historians of science in Greece. Stephanides's successor to the Chair of History of Science, Christos Papanastassiou has left no work.

Nevertheless, during the decades that followed the retirement of Stephanides, history of science has a presence, although weak, in Greek publishing.

In 1940, Konstantinos Mermigas published his *History of sciences* which no longer insists on the greatness of the antiquity but on the achievements of modern times. Namely, only 350 out of the 500 pages of his book are about classical science.

Fifteen years later, another book was written by K. Logothetis[2]. This book was a series of biographies of men of science and philosophers, in chronological order and without any connection between them. The interesting fact is that this

[1] The Ottoman Empire controlled at that time several islands, including Lesbos Island the birthplace of M. Stephanides.

book was published by the 'state organization of school textbooks', which opened the door of secondary education for the distribution of the book as a valuable reading for teachers.

Neither Mermigas nor Logothetis were historians of science and their books were merely historiographical compilations. At about the same period Evangelos Stamatis edited and published brilliant works of Archimedes, Apollonius and Euclid. Stamatis was a secondary school teacher and had studied Physics in the 1930s in Germany. Very reactionary in his political beliefs, an admirer of the ancients, he published in the 1970's excellent editions of these three scholars of Antiquity. His works enjoyed the support of the 'state organization of school textbooks' and of the Chamber of Technology of Greece (Chamber of Engineers). With Stamatis a whole era is coming to an end. Stamatis is the last of a generation of historians of science who worked most of the time in isolation from the international community of historians of science.

The notion of "neo-Hellenic Enlightenment" and the study of "reception"

In the late 1970s after the fall of the dictatorial regime (1967-1974), an innovative spirit arose on the scientific community of Greece, with the arrival from abroad, where they were in voluntary political exile, of scholars who had established a career in European Universities.

Among those the most prominent figures were Yannis Karas, Nicolas Svoronos, Kostas Krimbas and Eftychis Bitsakis. With their arrival, we see in Greece the birth of a community of historians of science that will quickly develop in the next three decades. The common characteristic of this generation is its affiliation to the left which at that time, in response to nationalist ideas of the military junta, wanted to cease its links with the "glorious past" of antiquity and Byzantium and promoted the study of modern and contemporary issues. Moreover, it was this leftist political affiliation, which in the context of the critical science of the 1970s, motivated these scholars to be interested in the philosophy of science as well as its history.

The decade of the 1980's, gave birth for the first time to a scientific community of historians of science in Greece that was incorporated in the corresponding international community and which followed international research trends in the field.

This new generation considered the argument for the continuity as an ideological construction and turns its attention to the study of the period that has been called "Neo-Hellenic Enlightenment" and focuses on the study of the reception and assimilation of the ideas of the 17th century scientific revolution in the Hellenic communities.

Yannis Karas initiated the aforementioned field studying the development of science in Greece during the time of the Ottoman domination. He was employed in the Centre of Neo-Hellenic Research of the National Hellenic Research Foundation where he established the Research Program "Influences of the European Scientific Thought in the wider Greek and Balkan region". Karas turned his attention in what has been called "Neo-Hellenic Enlightenment" (the reception and assimilation of the ideas of the 17th century scientific revolution in the Hellenic communities). His work incorporates research on primary sources, connections of the history of sciences with the political, economic and ecclesiastical history, connections with the philosophical currents and the international political developments.

Indeed, Mathematics, Physics, Biology, Geology, Geography, Astronomy and Medicine have been studied by the Greek scholars of the 18th century, at a level that cannot be considered as elementary. Recent research has shown that the Greek scholars of the 18th century worked on an ideological "project" in order to enlighten the Greek speaking communities of the Balkan region and to guide them to a national revival, which was also scientific, social and political (Nicolaidis 2010).

Greek scholars of the Enlightenment considered that the Greek communities of the Ottoman Empire (belonging to the scientific periphery of Europe) should prove that they were a component of the western civilization. These scholars tried to transfuse in these communities the knowledge they acquired during their studies in European universities.

The scholars of the periphery are not passive agents whose only function was to distribute locally the knowledge delivered to them from the centres of Europe, but rather as active subjects who received no particularly clear directions on how to dispose of them locally.

When we examine issues of reception it is required to discuss the ways in which ideas that originate in a specific cultural and historical context are introduced into a different one with its own intellectual traditions as well as political and educational institutions.

The issue of reception of western science in the Greek speaking communities of the Ottoman Empire is part of a discourse that has developed internationally during the last decades, concerning the ways of diffusion of the dominant western science and technology. There is also a growing interest on comparative studies of the different scientific and technological traditions of the peoples of the world. The approach of these themes is not limited only in recognizing the

[2] "The Philosophy of Renaissance and the Foundations of Modern Physics" (1955)

cultural "specificities", but it goes further on to examine and reveal the relations of power and dependence, as well as the uses of science by the dominant social classes (Blay and Nicolaidis 2001).

Whether this project will be successful remains to be seen, given the controversial nature of factors involved, whither institutional, political, ideological and/or scientific. What is beyond any doubt however is the will of researchers involved to carry out the project whose importance transcends national borders and can be considered as a model case for other countries of the European scientific periphery.

Karas and his research associates in NHRF have organized a series of Conferences in the 90's focusing on the reception of the ideas of scientific revolution in Greece. When Karas retired his work has been continued by Efthymios Nicolaidis as the Head of the Program of "History and Philosophy of Science" in NHRF.

In the beginning of the 1990s, the growth of Greek Universities, allowed members of the community to create new institutions, apart from the already existing National Hellenic Research Foundation and the National Technical University of Athens. The culmination of these developments was the foundation of the Department of History and Philosophy of Science in the University of Athens and the publication of the journal *Neusis*.

During the 1990s also, the Department of History and Philosophy of Science in the University of Athens, initiated the project *"Hellinomnimon"* under the supervision of Prof. C. Gavroglou. This project, which has assisted greatly in the research on the reception of scientific theories in Greece, consists of a collection, in digital form, of all the writings of the Greek scholars of the 16^{th} - 18^{th} century and has been constantly enriched. The same group also participates in STEP (Science and Technology in the European Periphery) an international research group focused on the study of processes and models of circulation of scientific and technological knowledge between European centres and peripheries from the 16^{th} to 20^{th} century[3].

The issue of "teaching"

After 2000, a new group research group appears in the Greek academic scene called "History, Philosophy and Didactics of Science and Technology" – HPDST. HPDST originates from two complementary groups, the History and Philosophy of Science and Technology group of the National Hellenic Research Foundation and the group for the Didactics of Science of the Department of Education of the University of Athens. The merge was brought through the acknowledgment that there is a strong need for science to be re-established in society and engage its stakeholders. This goal is to be accomplished through state of the art research using an interdisciplinary approach. Since 2000, HPDST has developed into one of the most promising research teams in South-eastern Europe.

The epistemological issue arising is whether these two Disciplines i.e. History of Science and Didactics of Science can complement each other. The main question one may ask is: Whether Teaching of the History of Science in the science classroom is legitimate.

The first attempt to fuse these two research traditions mentioned above following developments in Greek Science Education was made by Andreas Kassetas, a secondary school physicist.

The second attempt was made through the organization of a series of Conferences in Thessaloniki (2001), Athens (2003), Athens (2005) and Patras (2007). These biennial conferences have been complemented by a series of other initiatives such as the formalization of the "Hellenic Society of History, Philosophy and Didactics of Science" following the Meeting organized in Athens in September 2007.

In the autumn of 1980, during the 2nd National Conference of the Hellenic Physical Society, Andreas Kassetas made the first reference for the need to incorporate elements from the history of physics in physics teaching in Greece. Which were the theoretical milestones of this proposal? According to A. Kassetas' own writings his theoretical sources included: The antipositivism of T. S. Kuhn's Structure of Scientific Revolutions, Arthur Koesler's Sleepwalkers, Yannis Karas' History of Greek Science, John Bernal's Science in History, Rene´ Taton's Histoire General des Sciences and above all the Harvard Project Physics Course.

A few years later, the Hellenic Physical Society appointed A. Kassetas and his team (his teacher in Athens University S. Mourikis and his friend and colleague N. Dapontes) to write a Physics textbook for the 10th and 11^{th} grade students (1st and 2nd grade of the Greek Lyceum). The textbook was written following the general line of the Harvard Project with certain variations and differences though, which reflect the originality of the authors' contribution in Physics Teaching. The textbook was endorsed by the Ministry of Education and was printed and distributed to "polykladika" Lycea. In the Greek educational system of those days there were two types of Lyceum: the "polykladikon" and the general. In the "polykladikon" Lyceum a

---

[3] Science & Education 15, Nos 7-8, 2006, Special Issue: Textbooks in the Scientific Periphery

student could follow specialized and more intense Physics courses while the General Lyceum was oriented more on general education.

There were fourteen "Polykladika" Lycea in Greece with nearly 10,000 students. Kassetas' textbook has been taught for 12 years (1984–1996) while the revised edition of the book was taught for another 4 years (1996–2000) in all the Lycea of the country.

Unfortunately, there was no official state committee to evaluate the outcome of this attempt. We have in our hands only one evaluation report from 6 Lycea in the Athens region based on a questionnaire distributed among the physics teachers of the corresponding schools. The structure of the questionnaire is fragmentary, reflects only the personal opinion of the teachers and there are no any quantitative data to support solid conclusions. However, the general feeling is that the majority of Greek Physics teachers were not adequately prepared to teach the historical material contained in the book, since they did not have any formal education in the history of science, or even any training in the logic of the Harvard Project before the official introduction of the book. Their usual tactic was to omit the historical information or the paragraphs dealing with epistemological matters.

Kassetas estimates that only about 30–40% of teachers felt comfortable with the book and embraced it wholeheartedly in its first phase. The growing opposition to the book led to its revision in 1996 when a lot of the historical material was left out and finally to its replacement in 2000 by another textbook (Skordoulis & Halkia 2005).

It is interesting to note though that the main argument against Kassetas' book was based on a naive empiricism advocating "the introduction of experiment" as the solution to any problem that Greek physics teaching faced.

In this context, it is not surprising that the introduction of a History of Science and Technology course, on a compulsory basis, in the Greek Lyceum in 1999, supported by a textbook written by staff of the Department of History and Philosophy of Science (Gavroglou et al.), faced harsh opposition from both teachers and students and it was made elective the following year.

Following these events, it became a common belief among scholars in the Departments of Education of the Universities of Thessaloniki and Athens that only a process of systematic teacher education and training on both undergraduate and postgraduate level in History, Epistemology and Didactics of Science linked with research work on the conditions that shape the educational environment from the 19th century onwards and in constant dialogue with the international community holding similar views can create a fertile ground for the success of HPST in Greece (Skordoulis 2009).

A vast literature already exists trying to answer this legitimate question. Summarizing, teaching history of science assists in Abolishing the "Two Cultures" Dichotomy, to show the students that science is part of human culture and that science is a human activity, to improve the image of scientists in Society, to change students' attitude towards science and also attract highly qualified students to science courses.

All the above may sound highly utilitarian. But does the teaching of the history of science in the science classroom bring an improvement in students understanding of the scientific concepts? Do students that have been taught history of science have a better understanding of basic scientific concepts than those who have not? Do they perform better in science courses?

This is hard to answer emphatically. What has been proved by research in the relevant field is that Teaching History of Science improves critical thinking and problem solving skills and students acquire a better understanding of the Nature of Science (NOS). The objections of colleagues criticizing the teaching of history of science in the science classroom are based on the ideas developed by Thomas Kuhn in his "Essential Tension" (1977).

Kuhn's main argument is that Teaching History of Science in the Science Classroom undermines the dedication of students to Normal Science, to the dominant 'Paradigm', and that history of science in the science textbooks is a pseudo-history i.e. a history of science that has undergone a Didactical Transposition. The notion of 'Didactic transposition' was firstly introduced by the French sociologist Verret (1975) and was used extensively in the field of Mathematics Education by Chevallard (1985). According to this classical approach, scientific knowledge is transformed to school science after specific educational system (institutional) actors have functioned upon it. Some years later, Martinand (1986) showed that it is not only the formal (institutional) educational system but also the social practices that play a crucial role in the didactic transposition of a scientific concept. More recently, Clement (1998) has added the value system as a determining factor in the didactic transposition.

It is a fact that after having gone through its phases of infancy i.e. admiration of the ancient science, history of science in Greece runs now a mature period where current research trends are integrated with those of the international community of Historians of Science and also of science educators. The HPDST group has developed partnerships with European research groups and built a network of historians of science and technology in South-Eastern Europe. To support these goals, the group publishes a bilingual journal (*Kritiki:* Critical Science and Education), an international journal (*Almagest*, International Journal for The History of Scientific Ideas) and the *Newsletter for The History of Science in*

Southeastern Europe. The role of this group in SE Europe has been further strengthened by support from the European Union for its future development (program Hephaestus, REGPOT 1-2008).

ON THE HISTORIOGRAPHY OF MATHEMATICS IN ITALY

Maria Teresa BORGATO
Department of Mathematics, Università degli Studi di Ferrara, ITALY
bor@unife.it

Abstract

The historiography of mathematics in Italy has a long tradition dating back to the Renaissance (Bernardino Baldi, 201 biographies in his Vite de' matematici*). Moreover, Italian scholars contributed to the transmission and history of science with translations, commentaries and editions of ancient classics, and chronologies were included in encyclopedic treatises in the sixteenth century.*
In a modern sense, however, the historiography of mathematics begins in the eighteenth century, when the history of mathematics was considered an area of the history of human thinking. In Italy it was initially developed as a part of Italian literature and inserted into general works (Giovanni Andres, Girolamo Tiraboschi). Critical analysis of mathematical theories and their historical foundations can be found in works of mathematicians like Joseph-Louis Lagrange, Gregorio Fontana, and Pietro Cossali. Giambattista Guglielmini, at beginning of the nineteenth century, provided, with his eulogy of Leonardo Pisano, a widely followed model in the historiography of the century: expositive text and extensive bibliographic notes. An important work, which combined general overview, technical and archival investigation came out later: the famous Histoire des sciences mathématiques en Italie *by Guglielmo Libri (4 volumes 1838-41). The historiography of mathematics developed in the second half of the century, after the political unification of Italy, with Baldassarre Boncompagni's foundation of the* Bullettino di bibliografia e di storia delle scienze matematiche e fisiche *(20 volumes), which supplied both an international diffusion and primary sources. Antonio Favaro was the editor of Galileo's collected works, and Pietro Riccardi published a bibliographic work still of great importance, the* Biblioteca matematica italiana*. In the first half of the twentieth century, two mathematicians became the main historians of mathematics: Gino Loria and Ettore Bortolotti. The historiography of mathematics in Italy has increased with the publication, from 1981 on, of the* Bollettino di storia delle scienze matematiche *(29 volumes).*

The historiography of mathematics in Italy has a long tradition which dates back to the Renaissance. Inaugural orations of the new academic year at universities cite lists of illustrious mathematicians and astronomers like that of Luca Gaurico in Ferrara in 1507. The sixteenth century has left us a wide biographical repertoire by Benardino Baldi on the lives of mathematicians. In the 17th century it was encyclopaedic works on mathematics which contained biographies and chronologies of mathematics, like those of Biancani, Riccioli, and Milliet Deschales. In the 18th century, the history of mathematics developed, as part of a more general history of culture, in the general works of history of literature like those of Giovanni Andres or Girolamo Tiraboschi. This century, however, saw the beginning of historical investigations of mathematical theories, and, at the end of the century, we find the extensive work by Pietro Cossali on the transmission of algebra to the western world (Parma 1797-98). The history of mathematics plays a role in the mathematical works of Lagrange, where long introductions and historical notes were often inserted to create a link with the research of the past, and present modern theories as their final evolution.

In the Napoleonic period research into the history of mathematics underwent several developments in the surge of a national feeling and the vindication of Italy's glorious past discoveries. Giambattista Venturi proposed the scientific work of Leonardo da Vinci, and a history of optics, Mariano Fontana the arithmetic of Maurolico, Giambattista Guglielmini made in-depth research into the figure of Leonardo Pisano and mathematics of the Middle Ages (Bologna, 1813). This line of research also continues for the Restoration period through the works by Pietro Franchini, and the passionate in-depth study of the history of mathematics in Italy from the Renaissance to the 17th century (1838-41) by Guglielmo Libri.

Political unification injected more vigour and encouraged the extension of studies of the history of mathematics. Three figures emerged whose works also provided the indispensible tools for the development of research into the history of mathematics: Baldassarre Boncompagni, Antonio Favaro and Pietro Riccardi, the tools being: a specialised journal (the *Bullettino di bibliografia e di storia delle scienze matematiche e fisiche*), publications of rare or unedited mathematical works (the National Edition of Galileo's collected works), a bibliography of every publication concerning the history of mathematics in Italy (*Biblioteca Matematica Italiana*).

At the same time the history of mathematics was further improved by some of the most illustrious scientists: Luigi Cremona, Eugenio Beltrami, and Felice Casorati, whose aim it was to retrieve the true origins of the theories they were developing in the works of mathematicians of the past.

Specific studies at the turn of the century included: the edition, by Federigo Enriques, in 1900, of a collection of mathematical theories introduced and developed historically, fundamental to the formation of teachers of mathematics (*Questioni riguardanti le matematiche elementari*); the first critical history of non Euclidean geometries by Roberto Bonola, contributions to the history of logic by Giovanni Vailati with his essay on Saccheri's work, and the first historical papers on ancient Chinese mathematics by Giovanni Vacca.

As for critical essays and books of the early nineteenth century, first of all mention must be made of Gino Loria, a mathematician by formation, considered the most notable historian of mathematics of his day. Continuing in Boncompagni's footsteps, he, in his turn, founded the *Bollettino di bibliografia e storia delle science matematiche* in 1898 and published texts which became classics like the history of descriptive geometry, the history of mathematics and exact sciences in ancient Greece, the theory of algebraic and transcendent plane curves. Ettore Bortolotti also had a mathematical formation and his major contribution was to the history of Renaissance and seventeenth-century mathematics, by publishing Ruffini's complete works and reconstructing the most successful discovery of Renaissance mathematics: the solution of cubic equations and the origin of complex numbers.

The last contributions of the first half of the 20th century were given by Ugo Cassina, on the history of Peano's logic, Ettore Carruccio, Attilio Frajese (the editions of Euclid's and Archimedes' work in Italian) and Ludovio Geymonat on history and philosophy of infinitesimal analysis.

In the research of these Italian historians of mathematics one common feature emerges: namely, that of underlining elements of continuity in the history of ideas, as if mathematics in Italy had developed along a continuous line with successive contributions of various authors. Their contribution to historiography of mathematics has already been remembered elsewhere, so I will concentrate on more recent research in this field in Italy.[1]

After the Second World War

With the reconstruction of the university system following the second world war, the study of the history of mathematics was once again taken up, which, like mathematical studies, had to get back into contact with the international output that had been interrupted by the war and the last decades of the fascist period. This break was less serious for the history of mathematics which, by tradition, concentrated studies on more antique periods and celebration of moments of national glory.

Studies of the history of mathematics were mainly developed in Rome, where the school of Federigo Enriques proceeded through his pupils: Attilio Frajese, above all, took over teaching of the history of mathematics when Enriques had been removed from his post as a result of the racial laws. Frajese's work as a historian of mathematics, consolidated in over sixty articles and various books, mainly dealt with the mathematics of Ancient Greece, and he was considered Italy's top

[1] For more details, see: F. Barbieri, F. Cattelani Degani (eds.), *Pietro Riccardi (1828-1898) e la storiografia delle matematiche in Italia*, Bologna, Tecnoprint, 1989; M.T. Borgato, 'On the History of Mathematics in Italy before Political Unification', *Archives Internationales d'Histoire des Sciences,* 42 (1992), 121-136; U. Bottazzini, 'Italy', in: *Writing the History of Mathematics: Its Historical Development*, ed. By J.W. auben, C.J. Scriba, Birkhäuser, 2002, 61-95.

expert in the field owing to his knowledge of ancient languages which allowed him to read texts in the original languages (Greek, Latin and Arabic). His profound knowledge of Greek mathematics of the Classic period led him to translate, in collaboration with Lamberto Maccioni, Euclid's *Elements* and the works of Archimedes. Linked to the Frajese school was the research of Silvio Maracchia, one of his pupils, who took up his position in the "Sapienza" in Rome.

In Turin, the tradition of the history of mathematics was carried on by Tullio Viola, above all in the field of mathematics in pre-history and the mathematics of ancient civilisations (Babylonia, Egypt etc.). Viola had been an assistant to Enriques in Rome, as well as Ettore Carruccio, who also belonged to the school of Federigo Enriques, taught history of mathematics at the University of Turin from 1955 to 1975, and then in Bologna. The main focus of his works on the history of mathematics was the history of mathematical logic.

Lucio Lombardo Radice is, perhaps, the greatest exponent of another way of dealing with the history of mathematics: a politician and mathematician involved in mathematics education, he wrote general histories of mathematics which were strongly influenced by his philosophical line of thinking (*La matematica da Pitagora a Newton*, 1971) as well as important translations (Nikolaj Ivanovič Lobačevskij, *Nuovi principi della geometria*, 1974).

In Lucca, Gino Arrighi, a scholar of mathematical formation and remarkable erudition, carried out research into a field which, largely unexplored at that time, later became very productive for the reconstruction of the mathematics of the Middle Ages and Renaissance period: the manuscript texts of the school of arithmetic which flourished in Tuscany, above all in Siena and Florence from the 13th to the 16th centuries. Arrighi published about twenty treatises and two hundred essays. Successive research works took up this line of study like those of other historians of algebra such as Laura Toti Rigatelli and Raffaella Franci, who, in 1980, founded the Centro Studi della Matematica Medioevale in Siena.

Another learned scholar, Angiolo Procissi, has left works on both the history of algebra and the theory of numbers, as well as bibliographical works; in particular we may remember the bibliography of the Galilean manuscripts preserved in Florence.

The number of universities teaching the history of mathematics, always as part of the degree course in mathematics, was very scanty in Italy. The history of mathematics was, moreover, considered as a complementary discipline to related subjects in the formation of secondary school teachers (foundations of mathematics, didactics of mathematics, complementary mathematics, elementary mathematics from a higher point of view), and generally as a less important discipline compared to pure and applied mathematics. The first university chair for the history of mathematics was given to Ettore Carruccio in Bologna in 1975, but it was left empty shortly afterwards due to Carruccio's having reached the age limit for such a post. Umberto Bottazzini was then awarded the teaching post but it was it was only several years later that a national competition for a chair in the history of mathematics was established.

Even at the beginning of the 1970s the number of scholars in the field was fairly restricted and output was limited to themes initiated by Enriques and a few strictly scholarly works. At the end of the 1970s, however, new contributions to the discipline were made by various scholars, often of strictly mathematical formation, who carried forward the history of mathematics autonomously. Reflection and evaluation of the output in this field was, therefore, imperative.

The historiography of mathematics, when it is not just a question of biography, chronology or bibliography, requires a specific formation; in Italian universities, since historians of mathematics mostly have a mathematical formation and teach the history of their own discipline, they often specialise in related sectors, such as, history of algebra, history of mathematical analysis, mechanics etc. If, on the one hand, this fact allows us a greater insight into mathematical principles on the basis of the different theories, on the other, the risk is a levelling out of the historical interpretation based on modern ideas and language and a disproportionate importance being awarded to the results of one or another mathematical school. Historiographic problems of this type were discussed in preliminary and general terms, when the community of mathematical historians in Italy got together to organise the creation of a national network of scientific relations and co-ordination.

A first step forward took place on the occasion of the conference held in Ferrara in 1981 on Gianfrancesco Malfatti, an Italian mathematician of the second half of the eighteenth century.[2] The initiative to promote these studies, by bringing together the various scholars who have made individual contributions to them, originated from two professors of mathematical analysis: Enrico Giusti and Luigi Pepe.

A second meeting on the history of mathematics in Italy followed in Cagliari in 1982, where an overview of the many different fields developed by Italian researchers and new themes, or new points of view, were presented.[3] A third meeting on critical editions took place in Trento in 1985.[4] This meeting highlighted the basic features essential to critical works: philological accuracy, with no concessions to modernizations and no direct intervention on the text, a body of essential

[4] *Edizioni critiche e storia della matematica*. Atti del convegno CIRM, Trento, 1986.

critical notes pointing out any possible errors without, however, free interpretation, painstaking description of the document reproduced, a sober introduction of the contents combined with a historical collocation of the work. While the aim of a critical edition of a text is to give scholars access to unedited documents or works that are difficult to retrieve, it would be more appropriate to discuss interpretation and speculation in essay form or apart in separate volumes. In this way the edition may maintain its validity for longer periods of time, even generations, whereas a historiographical analysis, even of high level, being linked to the author's personal view, requires continuous revision.

The debate continued in 1987, when a conference on the Italian historiography of mathematics took place in Modena, in which historians tried to define the long tradition of mathematical historiography in Italy, and reflect on the various types of historiography, their limitations and pertinence.[5] The main aim was to avoid the risks of an "ideological" history, examples of which are abundant in the recent international and national literature, when, in order to achieve originality at all costs, a thesis is established a priori and a secondary element assumes the value of a principle. A further goal was to avoid the limitations of parading one's learning or flattening history through the exaltation of the discoveries of Italian scientists, often resolved in the research of 'precursors' (this, too, is abundant in the contemporary historiography of various countries).

As may be seen, reflection on present and past production has led historians of mathematics to apply to their historical research, besides the principles of rigour and accuracy inherent to mathematics, those principles that guide general historical research, namely, accurate citations, adherence to the historical period in the interpretation of a work, collocating it in a wider context which includes the author's biography, his/her formation, the historical and social period and so forth. All these elements should be borne in mind, even if there are historiographic works with different aims; so far production includes: critical editions of works or correspondences, interpretations in essay form on works or authors, analyses of entire theories seen over the centuries, general histories covering all the mathematical disciplines centred on a particular historical period, histories of mathematics aimed at dissemination to a wider public, scholastic texts in which mathematics is used to introduce mathematical concepts in the classroom.

The successive period saw the output and study of the history of mathematics develop so much that Italy became known as one of the main centres for this type of studies; this development was consolidated in the organisation of several international congresses throughout the country and, above all, in 1981 with the foundation of a new international journal devoted entirely to history of mathematics: the *Bollettino di Storia delle Scienze Matematiche*. The journal, published by the *Unione Matematica Italiana* until 2000, was then taken over by "Il Giardino di Archimede", a museum of mathematics, at the time when the *Unione Matematica Italiana* became a member of the museum. The new series is published by Fabrizio Serra, Pisa-Roma, with Enrico Giusti as its director and Luigi Pepe, vice-director. The *Bollettino* publishes research on the history of mathematical sciences in a wide sense, to include the history of mechanics, theoretical astronomy, natural philosophy and other disciplines traditionally placed within the exact sciences. The *Bollettino* publishes essays and articles in Italian, English, French, German or Latin. In line with a traditional development in Italian historiography of mathematics, particular attention is given to the publication of unedited texts of particular importance to the history of mathematics, for instance, correspondence, bibliographical essays and archive research, and in general to the tools for historical research. The journal publishes two issues a year and, so far, 29 volumes have come out.

Italy publishes international journals on the history of science like *Physis*, founded in 1959 and published by "Domus Galilaeana" in Pisa, open to all possible aspects of the history of science and technology. *Nuncius* is the journal of the *Istituto e Museo di Storia della Scienza* in Florence, founded in 1976 under the name *Annali di Storia della Scienza*, which since 2011 has changed publishing company and editorial profile adding the subtitle: *Journal of the Material and Visual History of Science* in order to highlight the fact that along with the investigation and enhancement of primary sources the journal is devoted to the "history of instrument making, scientific heritage and more generally to the relations between arts and science". Other journals, like the *Rivista di storia della scienza*, published by the Faculty of Sciences of "La Sapienza", University in Rome, devoted to the history of mathematics and natural sciences (1984-1996), have ceased to be.

In 2001 the *Società Italiana di Storia delle Matematiche* (SISM: Italian Society of the History of mathematics) was formed; it is a free association whose aim is to stimulate research and study in the field of history of mathematical sciences by favouring meetings for its members, publications and the promotion and dissemination of the history of mathematics. Among its main activities is the organisation of a congress for its members to be held every year in a different Italian city; the official journal of the Society is the *Bollettino di Storia delle Scienze Matematiche*. The first President was Clara Silvia Roero and now is Luigi Pepe. At present there are about one hundred and eighty members (http://www.dm.unito.it/sism/).

Main areas of research

I shall try to give a description of the various groups and current lines of thought which present a wide range of interests, and I apologise to the authors cited for the simplification of my outline given the restriction of space available to me.

---

[5] *Pietro Ricardi e la storiografia cit.*

In Florence there is Enrico Giusti, whose main contributions have been to the analysis of the works of Galileo and the Galilean School: the doctrine of motion, the theory of proportions, Cavalieri's theory of indivisibles, as well as to the historical foundations of infinitesimal calculus. Enrico Giusti also deserves special mention for planning and setting up "Il Giardino di Archimede", a museum of mathematics aimed at arousing young people's interest in mathematics and the history of mathematics. He is assisted in the running of the museum by Raffaella Petti. The research group also includes Sandra Giuntini, whose main contribution is the edition of correspondences and documents of mathematicians of the seventeenth and eighteenth centuries, Elisabetta Ulivi, who, after her first studies on the Galilean School, devoted her attention to abacus mathematics and the abacus schools in Tuscany in the 14th-16th centuries, expanding the research carried out by Arrighi, Procissi and then by Laura Toti Rigatelli and Raffaella Franci. The research group collaborates with Pier Daniele Napolitani in Pisa, who investigated the transmission and reconstruction of science of the Greek Hellenistic Age by sixteenth century mathematicians like Luca Valerio, Federico Commandino and Francesco Maurolico; he is now supervising the national edition of Maurolico's works. Veronica Gavagna, after an initial research on mathematical correspondences of the early twentieth century, besides taking part in the scientific publications of the Maurolico Project, is now focussing on the mathematics of the Renaissance and post Galilean periods.

In Turin, Silvia Clara Roero and Livia Giacardi, two pupils of Tullio Viola, have devoted their research mainly to Giuseppe Peano and Corrado Segre, as well as to reconstructing the mathematical milieu of Turin through its main protagonists and the history of its university. Silvia Clara Roero, has, moreover, been working with Silvia Mazzone from Rome on the origins of infinitesimal calculus in Italy; Livia Giacardi on the history of non Euclidean geometry. Sandro Caparrini and Erika Luciano are also part of the Turin group.

In Rome, Giorgio Israel co-ordinates a group, of which Ana Millan Gasca and Luca Dell'Aglio are part, that has developed research on the history of mathematics applied to economics and social sciences, probabilities and statistics. Israel has, moreover, been working on the reconstruction of the mathematical milieu of the Fascist period.

Mathematics in Italy between the two world wars is also the subject of research by Angelo Guerraggio from the *Bocconi* University of Milan. He founded a journal of mathematics and history of mathematics for circulation among enthusiasts and teachers of mathematics called *Lettera Matematica Pristem* (in collaboration with Simonetta di Sieno). Massimo Galuzzi, working in the State University of Milan, has been researching the history of the solution of algebraic equations (Galois' theory), the School of Bourbaki and the historiography of mathematics.

In Milan, there are also Paola Gario and Umberto Bottazzini, the latter a historian of international renown who has focussed his research mainly on mathematics in nineteenth century Italy, and its relationship with the French and German schools. One of his pupils, Rossana Tazzioli, has devoted herself to the study of the history of non Euclidean geometries of that period and the first models of hyperbolic geometry. Paola Gario has studied the Italian school of geometry, with particular regard to Enriques and Castelnuovo, as well as the history of the teaching of mathematics and the formation of teachers of mathematics.

In Bergamo, Pier Luigi Pizzamiglio has devoted his studies to the bibliography and publication of classics, the history of scientific instruments, and the history of mathematics in relation to the teaching of mathematics.

The nineteenth century is also the focus of Paolo Freguglia's research at the University of Aquila, regarding the history of algebra and geometry in the 16th-17th centuries, the foundations of mathematics and logic in the 19th-20th centuries, the vector calculus and correlated theories (quaternions). Instead, the history of absolute differential calculus and mathematical physics of the late nineteenth and early twentieth centuries, and the foundations of the probability theory constitute the subjects of research by Luca Dell'Aglio at the University of Calabria.

At the University of Calabria the leading historian of mathematics is Luigi Maierù, whose investigations are above all linked to sixteenth century mathematics such as the criticism of Euclid's Fifth Postulate, the angle of contact and the theory of conics.

The Ferrara group is composed of Luigi Pepe, Maria Teresa Borgato and Alessandra Fiocca, whose main focus has been the mathematics of the eighteenth and early nineteenth centuries through the publication of numerous unedited works above all of J.L. Lagrange. Luigi Pepe has carried out research into mathematics in eighteenth century Italy and the Napoleonic period with particular regard to Gaspard Monge's missions in Italy, the dissemination of infinitesimal calculus in Italy, the history of the teaching of mathematics and the scientific institutions. Maria Teresa Borgato's interest has focussed on the Jesuit scientists of the seventeenth century, Lagrange's biography, eighteenth century actuarial mathematics, and mechanics and hydraulics of the Napoleonic period. Alessandra Fiocca has studied the science of waters in the Renaissance and seventeenth–eighteenth centuries, the history of the university and Libri's historical works.

Francesco Barbieri and Franca Cattelani Degani, in Modena, have contributed with archival research and the publication of correspondences to the biographies of mathematicians and historians of mathematics of that city (Pietro Riccardi, and Paolo Ruffini).

In Genoa, we have the group co-ordinated by Antonio Carlo Garibaldi, which includes Giuseppina Fenaroli and Michela Malpangotto: their research works have investigated the history of the probability theory, the history of mechanics and the publication of various correspondences between mathematicians.

In Naples (and then in Salerno) Franco Palladino has been studying the mathematics correspondences in the nineteenth century and the history of mathematical models and instruments. Romano Gatto has done research into the mechanics of Galileo and the Neapolitan tradition. Giovanni Ferraro, at the University of Molise, has investigated the theory of series, the integration theory and the theory of functions in the eighteenth century.

In Palermo, Aldo Brigaglia is the co-ordinator of a group, which includes Cinzia Cerroni, whose focus is the history of algebraic geometry as well as the *Circolo matematico di Palermo*, a famous journal that collected important contributions from European mathematicians. Pietro Nastasi also works in Palermo studying the history of the Institute for the Applications of Calculus as well as the history of institutions during the Fascist period.

Various Italian scholars have carried out their studies mostly in other countries: Niccolò Guicciardini in Great Britain, where he worked on Newton's theory of fluxions and the development of calculus in that nation; Marco Panza in France where he carried out research mainly on the eighteenth century; Rossana Tazzioli, presently in Lille, has studied the relationship between Vito Volterra and French mathematicians.

CROSS-NATIONAL AND COMPARATIVE HISTORY OF SCIENCE EDUCATION

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 47.

TWO WORLDS APART –COMPARING GREEK AND AMERICAN 19TH CENTURY SCIENCE EDUCATION

Konstantinos TAMPAKIS
University of Athens, GREECE
ktampakis@primedu.uoa.gr

Abstract

In this paper, I intend to describe an example where the study of science education in two specific national contexts can illuminate the formation and character of the respective scientific communities. Thus, I will try to compare the educational structures and institutions created in nineteenth century US and Greece and show how they interacted with scientific practice in each case. At first glance, these two social and political formations had almost nothing in common. USA was a huge but fragmented state, with abundant natural resources and clear ties with a European superpower. On the other hand, Greece was a devastated small country, emerging after four hundred years of Ottoman rule and struggling to modernize under heavy European influence and interference. Despite their many differences, I aim to show how both American and Greek science education drew aspirations from the same European pedagogical models and how this process contributed to the character of scientific practice in each country. The tentative proposal of this work is that the history of science education in these cases should be seen as the history of discipline construction and not just as the last and least function of a mature scientific community.

Educating future scientists in nineteenth-century USA

National histories of education are notoriously hard to produce and thus approached with reluctance. Even if we try to examine only how scientists were trained, a description of the American system appears as especially hard because the different strata of American education did not have parallel historical evolutions, firm boundaries or autonomous functions. In any case, after the American Revolution and by the time of Jefferson's death in 1826, American education would revolve around free press, popular schooling, patriotism and the mobilization of a host of voluntary associations, such as political parties and clerical institutions (Chemlin 1980, p. 105-112). By 1850, different educational theories started to be incorporated in secondary and higher US education. The travels of educationalists such as John Griscon and William Woodbridge had brought Pestallozian pedagogy in the American classroom, especially in the academies, which were at the peak at the time (DeBoer 1991, p. 18-24). Johan Heinrich Pestallozzi had developed a system of teaching that drew heavily on J. J. Rousseau's 'Emile', emphasizing among others sense impression, experimentation and reasoning over memorization. These new methods were much more favorable to the new ethics of science, as they were being articulated at the time by speakers such as Huxley and Spencer, who, it must be noted, had also drawn explicitly on Pestallozzi 's work. Finally, Pestallozzian education was in turn eclipsed by the advent of Herbartian pedagogy, which by the 1900 was the most influential theory of education in continental Europe and beyond.

Prospective scientists were to be found in all educational institutions. The English School and the urban primary school formed the most basic education (Rury 2005, p. 70). Attendance of a public school of that level usually meant textbook driven teaching, terms defined by the demands of the local agrarian economy, amateur and transitory teaching staff and a fuzzy curriculum that could change in accordance with the idiosyncrasies of the teacher (Joncich 1966, p. 671). Subsequently, in the academy and the American high school the textbooks, which students had to learn by heart, dominated the classroom (Herbst 1996, p. 38-51). However, secondary education also

displayed a high proportion of female students and the sciences were much more easily found in female schooling than in male. The motto 'Classics for gentlemen, science for ladies' describes the situation accurately (Tolley 2003, pp.34-53).

Thus, scientific subjects were considered as having an inferior status in the context of the gentlemanly education. However, it is also a fact that the college curriculum had early on incorporated the natural sciences. Antebellum colleges actually employed a proportionally large number of men of science and taught natural sciences under the rubric of Natural Philosophy, by means of lectures dispersed with laboratory demonstrations (Guralnick 1974, p. 352-354)[1]. College admission did not require an examination of scientific subjects, but rather a firm grounding in the classics. These led future scientist of the nineteenth century to have a solid knowledge of the subject, many of whom saw it as an invaluable asset for their later career (Jonicich 1966, p. 681). However, physics, astronomy and a smattering of chemistry and geology was taught at junior and senior years. Recitation of the canonical textbook was how students were both taught and examined (Cremin 1980, p. 404-407). After 1850, the introduction of mathematics in the textbooks, the use of laboratories for teaching and the introduction of sciences in the sophomore year gradually became the norm, even as the colleges of old were transformed into universities. While the textbook was still the undisputed king of the classroom, new ideas would slowly be implemented that would eventually lead to the Research University of the twentieth century (Guralnick 1975, p. 60-77). But even then, the classics were still considered superior. Both trends can be seen in the following recollection (Millican 1950, p.14):

> "At the close of my sophomore year in Oberlin, my Greek professor, John F. Peck, asked me to teach the course in elementary physics in the preparatory department during the next year. To my reply, that I did not know any physics at all, his answer was "Anyone who can do well in my Greek class can teach physics.
>
> …I at once purchased an Avery Elements of Physics, and spent the greater part of my summer vacation of 1889 at home in Wichita, Kansas, whither Father had recently moved, trying to master the subject."

The American scientific community and education

We are now in the position to document the ways the evolution of the American scientific community followed the educational patterns of its time. First, we must start by noting that throughout the nineteenth century, the prime occupation of the American scientists was teaching. At least one third of American physicists, for example, were retained as teachers in primary or secondary education in one point or another of their career (Joncich 1966, p. 675). The teaching aspect of being a man of science was even more prominent in higher education. Antebellum colleges and later on academies offered courses on natural philosophy, chemistry and physics. These were usually taught by the same person, who stereotypically did not have specialized education in science[2] (Guralnick 1975). In the later part of the century, and despite the fact that science held a strong appeal to the 'common people' (Goldstein 2008), scientists active in research circa 1880 were less than 500 in a group of 3300 (Kevles et al. 1980). The rest mostly taught, an activity which also took the majority of the time of even prominent researchers. Teaching was not a peripheral activity for any scientists, and many did measure their scientific competence by their performance in the classroom (Joncich 1966, p. 683)

In the same vain, scientists for a long period doubled in both the role of the researcher and the popularizer, as the case of Benjamin Silliman shows. Silliman's popularizing lecture fees almost matched his Yale salary in the early decades of the century. His demonstrations requited visual aids and equipment, a fact that made him a firm supporter of the need of American instrument makers. This trend facilitated and in many ways led to the creation of a native instrument making industry (Warner 1988), which in turn enabled the subsequent emergence of the school and college laboratory. Object

[1] We must also note that chemistry was also taught in medical schools and high level physics was taught in West Point and engineering schools.

[2] Nor could he have. Graduate training, PhD degrees in sciences and specialized courses were to appear after the 1860 mostly in Germany and then mimicked across the world.

teaching, as advocated by Pestallozzian and later Herbartian pedagogy, was, after all, in full accordance with the demonstrative experiment.

A parallel process can be seen with science textbooks. If we bear in mind the predominance of the textbook as the main teaching device, it is important to note how American scientists progressed from textbook translators to textbook editors to textbook writers. Apparently, more than half of the men that taught mathematics and physics in antebellum colleges wrote or translated a textbook (Warner, p. 394). What the textbook contained determined significantly the curriculum itself. Thus, for example, when Silliman and later Denison Olmsted included experiments in their textbooks they in effect introduced them in the school curriculum. Again, textbook production was recognized by contemporaries as an important indicator of the strength of the scientific community (Millican 1950, p.14):

> "In the sophomore year I registered for a single twelve-weeks course in physics, using as a text a new American one by Anthony and Brackett, which we all thought both unintelligible and dull, greatly inferior to Ganot Physics, which had theretofore been used. For me the course was a complete loss.
>
> An indication of the state of advancement of American science at that time is found in the fact that so far as I know the only two physics texts then used at all extensively in American colleges were both translations from the French, namely, Ganot Physics and Dechanelles' Physics."

Finally, there is also a correlation to be made between the character of American science and the way it was taught. The period after Civil saw contemporary scientists recognizing a clear divide between 'pure' and 'practical' knowledge. 'Practical knowledge' and experiment was the field where most American scientists pursued internationally acclaimed research. Even in physics and chemistry, US scientists usually acquired renown for their observational and experimental skills (Kevles 1981). This could be in fact far from a contingent matter. On the one hand, scientists, as we saw, were mostly a product of higher education. American college curriculum was shaped by a strong emphasis on the classics, as well as a pedagogy which insisted on the formation of concepts as the main focus of teaching. Moreover, sciences such as physics were seen and taught as a finalized discipline, with only measurements remaining to be complete. It was thus a very appropriate subject to be presented through a textbook. As a result, scientists involved in 'pure' science were inclined to develop the mentality of a classicist, whose subject matter is not expected to evolve beyond some parameters. On the other hand, the emphasis placed on object teaching and observation would naturally lead to experimentation as a suitable research avenue. The result would be a scientific community predisposed towards observation but also conservative in its applications and reluctant to stray in speculative theorizing. And in fact, this is what we mostly see in the late nineteenth century. As an endnote, we could also point out how the well established rapid entry of women in science during the post-Civil War period could be partially correlated with the relatively high proportion of science subjects in their secondary education. (Tolley 2003, pp.34-53). Thus, the way scientists were educated comes across as especially concurrent with their research practices. Science education in the USA, far from being an auxiliary activity, comes across as a major formative and normative dimension of disciplinary emergence.

Sciences and the Greek educational system

In many ways, education in the modern Greek State followed a symmetrically different timeline than in the USA. From the start, it was centralized and under state control. The pedagogy instituted by the first Governor Ioannis Kapodistrias in 1828 was explicitly Lancasterian, through its French reformulation by Louis-Charles Sarazin (Papadaki 1992). The net result of his efforts was the multiplication of the number of primary schools in both mainland Greece and in the islands. The curriculum, under the influence of a Sarazin inspired manual, included mainly grammar, reading and writing and religion. The main focus was on the creation of a widespread public primary education system, with only a few higher vocational schools, such as the Military Academy and the Κεντρικό Σχολείο (Central School) of Aegina (Kyprianos 2004, pp 75-81). Thus, the textbook was the central teaching tool.

Following the assassination of Kapodistrias, Greece was placed under Bavarian Regency in 1833, which imposed the system of public education that was to remain in effect for the next ninety years. The three-tier structure which came into effect consisted of a primary school, the Hellenic School and the Gymnasium as secondary schools and finally the University and the Polytechnic School, as higher education institutions. However, educational matters, despite the fierce debates they provoked, were in reality not treated as central. Generally, the policy pursued was tacit rather than explicit, mostly consisted of the uncritical adoption of European laws and an insistence on a strong public education, following the examples of Prussia and France. (Mylonas 2000). Primary education was not significantly altered and thus sciences never got a stronger hold on the curriculum until the end of the nineteenth century. It was in the newly founded secondary education that innovations appeared. In the Royal Degree of 1837[3] the curriculum described for the Hellenic School and the Gymnasium allocates two or, in some classes, three hours per week to Natural History, Chemistry and Physics. However, no further explanations or guidelines are given, nor is a specific textbook mentioned. As a result, these lessons faded into obscurity, until in 1855, another Royal Degree changed the curriculum, allocating two hours per week to Natural History in the first classes of Hellenic School and another two hours weekly to Experimental Physics in the Gymnasium. This was an effort to create a more plausible educational scenario, as for example, many successful Greeks of the Diaspora left large grants for the establishment of laboratories and institutions, but the lack of approved textbooks and qualified teachers did not enable their full use. It would take another twenty years for a more analytic science curriculum to appear and specific textbooks to be approved. In any case, natural sciences in the Greek curriculum never occupied more than two or three hours per week.

In 1862, King Otto I was evicted from his throne and one year later the Danish Prince George succeeded him. He was to remain in his throne until his assassination in 1913. During his period, Greek intellectuals more and more turned to German institutions for inspiration. Primary education once again became the focus of all educational reforms, where the monitoring school of Sarazin was replaced by the German pedagogy of Johann Friedrich Herbart. However, the adoration of all things Western of the past was no more. Actions taken by both France and Britain during the Crimean War had made the Greek population very suspicious of everything European. It was around this period, namely in the decades from 1865 to 1895, that specialized natural scientists start graduating from the Faculty of Philosophy of the University of Athens. It would however require another twenty years for them to be recognized as the only qualified to teach natural sciences in secondary education.

It was thus only in higher education, in the University of Athens and in the Military School, that sciences had a specified, albeit minor, role. The Physical and Mathematical Faculty in the University of Athens operated under the aegis of the Philosophy School. For the whole of the nineteenth century, there was only one Chair of Physics, while most of the subjects taught were heavily focused on Natural History (Stefanides 1948, Vol A, pp. 4-22). In any case, there were never more than ten professors of natural sciences in the teaching staff of the university.

Turning now to the Greek scientific community, it is immediately noticeable that most of the Professors of the University of Athens had studied in prestigious European universities, such as those of Paris, Munich and Berlin. They also remained in contact with their peers in Europe and took part in international conferences. Their main occupation, however, was teaching. Not only do they appear quite vocal when their teaching fees are threatened, but they also frequently write on the need to attract more students in their respective disciplines. In return, the public sees them as esteemed teachers and their role in establishing 'Greek science' is always related to their teaching achievements[4]. Furthermore, despite some initial ambivalence towards secondary education during the Bavarian rule, the second generation of professors active from 1860 onwards are quite firm in their insistence that science needs to be part of the curriculum and that only trained scientists should teach science courses. Once again, legitimization and autonomy for the scientist is reflected in their role in public education.

This process is nothing if not explicit. Scientists early on take on the mantle of the textbook writer, first for higher education and later on, for primary and secondary education also (Tampakis &Skordoulis 2010). The textbook becomes an invaluable symbol of authority on the subject and a valuable way to augment one's income. The importance placed by the scientists themselves on textbook writing can be seen by their very public debates when one of their textbooks did not make the official list of approved school books[5]. Moreover, it was not uncommon for scientists to get attacked by rivals not on the basis of their research, but on the flaws of the textbooks they had written (Kritikos 1995).

Finally, in the case of Greece, the reciprocal relation between the creation of a public science education and the emergence of a scientific community becomes forcefully apparent when the demographics of science are considered. It is no contingent fact that, from 1838 to 1865, no university graduate had specialized in natural sciences. On the one hand, the agrarian and mercantile nature of Greek economy did not readily create a social demand for science. Physics, Chemistry and Natural Science remained for the most part of the century a rather esoteric corpus of knowledge, warily accepted as necessary by the cultured elite for nebulous reasons having to do with modernity and progress. On the other, secondary education offered science courses only in name, while the centralized and hierarchical structure of Greek education did not allow for different avenues to higher studies. In a very real way, the lack of science education prohibited the emergence of Greek scientific practice. And indeed, the scientists of the time were either coming from abroad or had a direct relation with a scientist of the older generation. However, with the institution of an actual secondary science education in 1865 and with the

[3] All Royal Degrees mentioned in our discussion, as well as a comprehensive statistical analysis, are to be found in the first volume of Antoniou 1989.

[4] The reference to the teaching ability of a Professor as a measure of his worth is a recurring theme in the honorary speeches given on the occasion of his retirement. We find in the commemorative volume in honor of Prof. Mitsopoulos in 1901, of Prof. Christomanos in 1906, of Prof. Damvergis in 1917 and in the article written to honor Prof. Stroumpos by his successor T. Argiropoulos in 1890.

[5] As was the case, for example, with Prof. K. Mitsopoulos' textbook on Geography in 1894 and with Sp. Papanikolaou 's textbook on Physics in 1906. In both cases, furious public debates with leaflets ensued between the two contestants.

appearance of state approved textbooks, the University produced more than 30 science specialists within the next years. Science education in Greece not only went hand in hand but actually facilitated the creation of the Greek scientific community.

Conclusions

In this paper, I tried to show how scientific practice and education interacted in two different national contexts, that of nineteenth century USA and Greece. My ultimate goal is to suggest an alternative to the standard view that science education comes after the formation of the scientific communities or to put it bluntly, science education is what scientists do when they are away from their laboratory or conferences. In two specific cases, the picture that emerges is rather one of parallels, dichotomies and mutual construction. USA and Greece had a radically different social, economical and political timeline, which affected decisively the constitution of their educational and scientific space. But even while nineteenth century Greece and USA appear as two worlds apart, some striking similarities and parallels can also be noticed that suggest a larger picture. In both countries, men of science mostly taught, in higher, secondary, even primary education. The way they saw themselves and they way the public perceived them was tied to their educational activity, be it formal or popularizing. Thus, despite the historiographical blind spot that makes histories focus on pioneering researchers, most scientists of the era were engaged more with the classroom much more than with the laboratory or the field.

Furthermore, scientists were significantly more inclined to write textbooks than research papers. The development of native textbooks followed the development of the scientific community much more accurately than research publications. The strength of the scientific community was implicitly if not explicitly judged by the merits of its textbooks and scientists themselves were quite aware of the serious role that textbook writing had to play in the formation of their respective disciplines. Furthermore, especially in the US, something similar happened with the scientific instruments: the need for exhibition equipment made scientists into supporters of local craftsmen, which in turned helped scientific instruments to appear initially in the classroom and then in the research laboratories. In Greece, where instruments were not manufactured locally and scientists disassociated their role inside Greek society with their role as active researchers, textbook production acquired a highly visible role, with scientists being judged publicly by the merits of the school books they wrote.

Finally, the character of the ‘national’ science education appears to have had a formative role in the character of ‘national’ scientific practice. American scientists come across as very much influenced by their classical training, by the role that prevalent pedagogy gave to observation and object teaching and by the dominant role of the textbook within their classes. In Greece, the formation of the scientific community actually followed by almost twenty years the establishment of science in the curriculum. Even if it is a case of correlation rather than causation, the fact remains that it was only after public education expanded significantly enough for science to reach students that scientists started to appear in significant numbers. And when they did, the one common theme they had was their insistence on exclusive teaching rights.

KNOWLEDGE DIFFUSION AND THE LEARNING OF PRACTICAL KNOWLEDGE: CASE STUDIES OF EARLY MODERN JAPAN AND EUROPE

Simona VALERIANI, Mina ISHIZU

S.Valeriani@lse.ac.uk
M.Ishizu@lse.ac.uk

Abstract

The paper concerns comparison of the roles played by texts and objects in higher education in Western Europe, China and Japan in early modern period. As is well known in Europe the interest for the direct study of nature and properties of material objects grew during the sixteenth and seventeenth centuries. Although the use of these resources in practical teaching was limited, this type of sensorial teaching method increasingly gained its importance in educational theories. Texts and objects also shed a light upon the understanding of teaching traditions in contemporary Tokugawa Japan. While reading and interpretation of Confucian texts dominated the core part in the traditional curriculum in the Japanese elite schools, Western learning particularly medicine and military techniques were increasingly incorporated into practical teaching in higher education from the late eighteenth century. The paper also examines the contrasts and interactions between this new type of teaching with traditional Chinese teaching, that is, reading and interpretation of classical Confucian texts in the sixteenth and seventeenth centuries.

Introduction

In his book *Matters of Exchange*, Harold Cook writes: 'The powers and pleasures of accurate descriptive knowledge were not only praised by the chief advocates of the new philosophy' but were 'also noted as the chief concern of European science by others such as Japanese scholars who interested themselves in such matters'.[1] Cook illustrates this point with reference to the intellectual exchanges between a Dutch East India Company surgeon and the Japanese scholars in the second half of the eighteenth century. During the Tokugawa period (1603-1868), the Tokugawa government relatively effectively controlled its nationals' direct contacts with Europeans between the 1630s and 1858 under the semi-seclusion

[1] Cook (2007), p. 410.

policy. By granting the official trade monopoly to the Dutch, the government kept away the Catholic Christian missionary influence from Japan. Officially no Japanese people were allowed to travel abroad and the imports of foreign publications were under strict censorship of authority.

However, through Nagasaki, where the Dutch East India Company's factory was located, European culture especially its scientific and technological knowledge diffused in the Tokugawa period and it later played an important role in Japan's rapid assimilation of Western modern technologies in the subsequent industrialisation in the nineteenth century. The Dutch contact gave Japan the advantage of acquiring not only the Dutch origin culture but also more widely the latest scientific and technological knowledge. The Dutch Republic as a political power played a leading role in European cultural life and - with extensive activities oversee - stood at the centre of a worldwide network for commerce and the exchange of information. For example, Swedish Carl Thumberg, who arrived in Nagasaki in 1775 as the Dutch Company's surgeon, studied botany under Linnaeus at Upsala University before joining the Dutch East India Company. His time in Japan was spent collecting data of Japan's natural history and receiving frequent visits from Japanese naturalists and scholars who came to converse about European books and particularly European medical knowledge.[2] The paper will argue that the development of indigenous practical and utilitarian science in Japan played an important role in the intellectual interaction with the Europeans. Between the 17th and the 18th century, both in Japan and Europe we see developments in the attitudes towards nature, and to certain extent educational tradition that are highly comparable. The paper will analyse these phenomena focusing on their intellectual and social origins in both regions.

Useful knowledge: Japan, the Dutch and the Chinese tradition

An orientation towards empirical knowledge of natural world was evident in the knowledge circulation in the Tokugawa period. The *Genroku* era (1688-1703) witnessed significant increases both in agricultural and industrial production and the arable margin was extended significantly by irrigation. Productivity increased through more intensive application of fertiliser and human labour. The rise of commercial economy promoted the institutionalisation of artisanal skills. Agronomists often under the patronage of local fiefdom lords published agricultural treatises, *l*ocal almanacs and technical manuals.[3] The late seventeenth century agronomist Miyazaki Yasusada (宮崎安貞) spent thirty years travelling to collect and record agricultural techniques across western Japan and used this knowledge in experiments on his own land. His enterprise culminated in the agronomical treatise called *Nogyo Zensho* (農業全書) in 1697. Unlike the Chinese model agronomical treatise *Nose Zensho* (農政全書) (1639), written by the Ming court scholar徐光啓 and based on bibliographical records, Miyazaki's treatise drew upon his observations and experiments which included techniques with Chinese origins used by Japanese farmers. Miyazaki's treatise was printed and widely circulated across the country and promoted the accumulation of knowledge on agricultural production[4].

It is our thesis that Western sciences were so appealing to the Japanese because the two scholarly communities, different as they were, did share common tendencies and interests, namely in a new development of science that would be more practical oriented and would more closely analyse and take as a starting point for enquiry the natural and material world.

It is well known that in Europe from the sixteenth century a more practically oriented kind of scholarship, that will culminate in the so-called scientific revolution, started to take foot. This change of focus –compared with the medieval tradition– happened gradually and involved many different spheres. A part from the well known developments in philosophical and "scientific" circles, part of the discourse in fact took place amongst educational reformers. John Amos Comenius (1592 –1670), one of the most famous European pedagogists of the time, urged –for example- a change in the subjects being taught. He reflected upon the necessity to confront students of all grades with the natural world, material objects and practical problems. He underlined this when describing the ideal curriculum of the Latin school, the school that would prepare for University. "The pupils should learn four languages and acquire an encyclopaedic knowledge of the … seven liberal arts, a knowledge of which is demanded from a doctor of philosophy. But our pupils must aim higher than this, and in addition must be Physicists, who know the composition of the earth, the force of the elements, the different species of animals, the powers of plants and of minerals, and the structure of the human body, and who, beside knowing these things, can apply them to the various uses of life. Under this head is thus comprised a part of medicine, of agriculture, and of other

mechanical arts"[5]. The great importance given to the new sciences and the study of nature can be seen also in the fact that Comenius dedicated a whole chapter to "The method of the sciences, specifically", in which he stressed the importance of direct observation and of experiencing with the senses the materiality of things.[6]

Comenius was a protestant Czech teacher, and later became a bishop. As a consequence of the religious wars he was forced to live and work in many different countries. In the long run he was very influential for educational theory and practice in Europe and beyond although his principles were scarcely put into practice during his life time. His work however shows that the inclination towards the study of the material world through observation (put forward in the same period by figures such as Bacon and Descartes) was a feature that did not attain only the most advanced natural scientist and philosophers but was felt more broadly and started to percolate, even if very slowly, towards a wider audience.

Books: from people and objects to texts

Japan's encounter with Western knowledge was established both through books and through direct contact with practitioners coming to Japan as VOC officials. While the VOC had earlier employed mere 'barber surgeons' (with ambition to achieve a quick fortune from smuggling in East Asian trade), later the company recognised the value of both practical and academic training offered by Dutch Universities and selected young physicians with university qualifications. These men turned out to be highly appreciated by their Japanese interlocutors. The VOC even received an official request to bring to Japan someone who would have a more grounded understanding of medical matters and was not a mere practitioner[7].

Precisely speaking, Chinese translation of western texts was the initial and main source of western scientific knowledge. Despite the strict censorship of the Bakufu's Nagasaki Magistrate, some foreign books kept coming in. Order was made almost annually throughout the seventeenth century to Chinese merchants and the VOC to supply with books on practical subjects such as medicine, history and world geography. For example the Neo Confucian scholar Arai Hakuseki 新井白石 (1657-1725) studied world geography using many Chinese translated Jesuits texts.

Before the 1730s, most of the imported Dutch language books seemed to have often gone into the shogun's court library without being used. Occasional references by curious shoguns and their court members were recorded: particularly favoured were herbal and zoological texts such as Dodonaeus' *Cuijdeboeck* (1554) (presented to the Shogun Iesada in 1618) and Jonston's zoological treatise (Jonston 1660 presented in 1663). The shogun and domainal lords sometimes requested books on medicine and botany "with many illustrations" and "preferably in Portuguese."[8] The supply of books came from Amsterdam, the most active book trading centre in Europe, via the Company's Factory in Batavia.

The imports of foreign books increased from the relaxation of the rule in 1726 when the eighth shogun Tokugawa Yoshimune ordered over three hundred Chinese and Dutch texts on western science and practical subjects. Although Chinese texts remained the main source of Western knowledge, the mastering of Dutch language was encouraged. Yoshimune appointed the herbal scientist Aoki Konnyo 青木昆陽 (1698 -1764), who was trained in the Jitsugaku tradition at the Kodigo academy in Kyoto, and ordered him to learn the Dutch language to study its texts. By mid eighteenth century, the usefulness of European science became recognised not only by its advocating scholars but also by Tokugawa politicians. The distinguished government councillor Matsudaira Sadanobu 松平定信(1759-1829), wrote: "In the barbarian countries they know much about principle: especially in astronomy and geography and armament, or internal and external cures there is much one can profit from."[9]

Ordering nature for a purpose: Chinese, Japanese and European taxonomies compared

The following case study relates not simply to an increased production of compendia of useful and practical knowledge in the period, it represents the transition from Chinese originated practical manuals to Japanese vernacular publications. In the medieval period, when encyclopaedias (its East Asian term *Ruisho* 類書) came from China, Japanese versions were published following the Chinese model. These volumes were primarily hand-copied for the personal libraries of court aristocrats and used mainly for reference in reading Chinese poetry and Confucian texts. Ten collections of such reference works appeared between the late tenth and the sixteenth centuries but seldom contained information relevant for material production. In contrast, the early and mid Tokugawa period (1610-1739) saw the publication of some fifteen printed

collections of encyclopaedias and compendia of herbal and geographical data.[10] Advanced printing techniques, the expansion of a reading public through basic schooling were behind this movement, but of foremost importance was the desire to make knowledge accessible.[11]

Of particular interest is *Yamato Honzo* (大和本草) (1708) by the Confucian scholar and herbalist Kaibara Ekken (貝原益軒) (1630-1714) which was designed for the utilitarian ordering and understanding of botany and the properties of herbal medicines. It was in fact a Japanese version of a Ming model *Honzo Komoku* (本草綱目) (1590) but Kaibara clearly intended to make his version more relevant to production. For example, he paid much attention to agricultural products as well as herbs and flora of China and Japan. Learning from the Ming text, Kaibara modified the Ming classification into a more suitable one for Japanese use. He made a more precise classification of the items according to their locations – mountains, rivers, seas and land.[12] Kaibara served as Confucian official scholar to a local fiefdom lord in Kyushu. He frequently travelled on official duty to other fiefs. He held a position among the cultural and intellectual circle of Kyoto scholars, with useful connections to Kyoto publishers of collections of "Ekken books" drawn from Kaibara's practical knowledge and observation.[13] Furthermore Kaibara wrote most of his books in simplified Japanese letters – as opposed to philological Chinese contained in many texts circulating in Tokugawa Japan. He ordered their contents alphabetically. His clear intention was to diffuse useful knowledge, in an accessible form, to Japan's medical, technical and manufacturing professions.

The publication of these 'practical' compendia can be connected to an array of governmental initiatives put into place as a reaction to large trade deficits Tokugawa Japan was suffering in relation to China and Korea. Growing consumption amongst urban residents for imported goods such as silk and medicinal herbs had led to the drain of silver from Japan. As a result the Bakufu shifted its economic policy in a mercantilist direction. The need to increase the domestic production was identified and policies of import substitution were initiated. The government's establishment of the Koishikawa pharmaceutical research institute in Edo needs to be seen in this context: scholars were sent across the country to collect unknown plants and send them back to the institute to be studied.[14]

In this initiative different systems of knowledge meet and intertwine. The herbalists involved in this project were, in fact, well acquainted with traditional Chinese herbal knowledge and botany. The plants and minerals they collected from across the country were tested and identified against Yamato Hozou, its Chinese original Honzo Komoku and other Chinese herbal texts. At the same time the shogun Yoshimune (1716-1745), himself a keen herbalist, eager to acquire the Western knowledge, ordered the herbalists Noro Genjo and Aoki Konyo to translate Dodonaeus' *Cruijdeboeck* which, as we have seen previously, had been presented to an earlier shogun in 1618 by the VOC yet stored in the court library unused. The accurate reproduction of plants by Dodonaeus through numerous illustrations had caught Yoshimue's attention.

A similar development of scholarly enquiry that produced encyclopaedic texts in response to economic needs can be observed at the same time also in Europe. Dodoneus' work, for example, had probably been chosen as a present for the Shogun because of the great success it had enjoyed all over Europe (it was translated into French in 1557, into English in 1578 and into Latin in 1583). This success originated not only in its intellectual and scientific interest but also in its practical usefulness. Similarly to what we have been describing for Japan, also in Europe there was an underlying economic preoccupation that fostered botanical works. In the case of Dodoneus we know that before finishing his famous *Cruijdeboeck* he published part of it in *De frugum historia*.[15] This was to comply with pressures made by many international friends interested in improving agricultural output through the selection of better varieties of grains alternated with the cultivation of soil enriching plants, apt to animal consumption.[16] A process that will lead to the agricultural revolution of the 18th century. Both in Japan and Europe we therefore see a rise of applied knowledge, particularly in the botanic field, driven by intellectual interests but also by economic preoccupations.

Botany is also an important discipline for the development of systems for ordering knowledge and differences between Japan and Europe need to be underlined. Between the 16th and the 18th centuries in Europe there is a large debate about plant taxonomy that will culminate in the establishment of the Linnaean system. From an utilitarian or an alphabetical

way of ordering plants slowly botanist moved towards a 'natural' division according to species and 'families', a division that was trying to reflect nature's order.[17]

This new generation of botanical studies developed as a consequence of the fact that scholars, who until the 15th c. had been using reference text from antiquity for their studies, noticed discrepancies between the plants described in those books and the ones they could see around them. This stimulated a new trend towards direct observation of the natural world that harmonised well with the general developments of natural philosophy from the late 16th and early 17th centuries. Alongside direct observation a further important point became the retrieval of local knowledge through consultation with peasants, whose nomenclature became used also by the intellectuals. The choice to use the vernacular had different backgrounds. It was related to the fact -just mentioned- that the knowledge displayed in the books was local knowledge compiled *in primis* for a local audience.[18] Secondly it often reflected the intent by Protestant scholars to push the use of the vernacular as opposed to Latin.

This trend away from alphabetical ordering in Europe is peculiar to botany. General encyclopaedias until the Middle Ages were organised thematically and the alphabetic ordering starts to take over towards the 17th century. This development is linked to the use of the printing press and the deriving new understanding of letters as 'bricks' building a word.[19] Moreover while early encyclopaedias tried in their structure to reflect the world and the way it had been conceived, by the 17th century it was felt that organising knowledge in an 'organic' system was beyond reach. The alphabetical ordering seemed, than, a feasible alternative. As observed for Japan, also in Early modern Europe technical reference books proliferate. From the 17th century so called Hard-word lexicons (which only explain unusual terms, often addressing technical and scientific matters) appeared, than dictionaries of specific disciplines became more common and finally the dictionaries of arts and sciences were developed.[20]

Conclusion

This paper has analysed how different cultural tradition meet in Japan in the 17th and 18th centuries and exchange ideas and practices about observing and classifying the world. Stress was placed on the understanding and describing of plants and the organization of knowledge about natural resources. More practical oriented, utilitarian taxonomical systems merged with cosmological traditions with a growing interest for details which took different forms in different cultures. Notions about what is useful became entangled with ideas about how to organize knowledge and to make it accessible to different users: from government officials to common citizens. In this context intellectual trends are strongly connected with the makeup of educational systems that, as we have discussed, developed between the 17th and 18th centuries, in different forms, both in Europe and in Japan.

Interesting similarities between the Japanese and the European case can be found: as scholars in Japan start 'adapting' traditional Chinese knowledge to the local situation, Europeans are adapting and appropriating knowledge from antiquity. In this processes of acquisition in both cases we observe a reverence towards the classical canon and, at the same time, an effort towards making that knowledge more 'fitting' and useful to the own place and time. Related to the attempt to produce more useful and widely usable knowledge we observe in both cases the rise of a more broadly understandable language (the vernacular in Europe and simplified characters in Japan). It seems that the success of these enterprises aiming at collecting and classifying knowledge leys not only in their intellectual value, but also in the fact that they produced instruments that can be used to solve economic preoccupations.

The similarities and differences in institutional terms remain to be analysed. An in depth analysis of the changing role of different actors such as the Shogun, the domain Lords and private academies in Japan as well as individuals, private enterprises, scholarly societies and the state in Europe will allow a better understanding of the dynamics underpinning these phenomena and their different outputs.

KNOWLEDGE TRANSFER AND THE JESUITS: COMPARATIVE CASE STUDIES OF EARLY MODERN JAPAN, CHINA, AND INDIA

Mina ISHIZU, Ting XU, Anjana SINGH
London School of Economics, THE UNITED KINGDOM
M.Ishizu@lse.ac.uk
T.Xu1@lse.ac.uk

Abstract

This paper concerns the comparative historical research of the cultural regimes of knowledge transfer in the early modern period. It compares the cultural regimes in China, India and Japan, which patronised or restrained the diffusion of the western scientific orientation introduced by the Jesuits missionaries in the sixteenth and seventeenth centuries. The periodisation accords with the late Ming (1368-1644) and the early Qing (1644-1911) dynasties in China, the early Tokugawa period (1603-1868) in Japan, and the Mughal Empire and southern princely states in India.

Introduction

The comparative approach of this paper accords with the recent development in theories of knowledge economy and innovation in historical analysis of the European path. In the past few centuries the Western Europe seemed to have benefitted from its distinctive cultural regime favoured to foster technological advancement.[1] Interesting questions then should be asked about the Eastern regimes. In the early modern China, India and Japan, when encountering the European scientific orientations, how did their regimes interact with it? Are there to be observed differences and similarities amongst them? If so, what light can they shed upon our understanding of the wider question? In this preliminary research, the paper will focus on the case studies of the knowledge transfer patterns of the Jesuits science and its outcomes.

India

In the case of South Asia, it has been argued that the making of knowledge was shaped by 'material, economic, and symbolic transactions between indigenes and Europeans'.[2] The indigenous, it seems, are often just limited to Brahmin

---

[1] Jacob (1997); Mokyr(2002).

[2] Raj (2007).

scribes. Although there was certainly a role played by merchants, peasants, consumers and artisans in the interaction, this is something that still needs to be researched.[3] On the European side of the interaction, the role of all such agents, in the transfer of knowledge, are well documented not in the least, the role of the Jesuits; to critically examine which, is the main aim of this section of the paper.

The role and continued vibrant contribution of the Jesuits on education in India, specially in higher forms of education, in contemporary India is indisputable.[4] The lack of sources to study indigenous forms of higher education in the Indian subcontinent makes it challenging to measure the character of their contribution historically. However, there are rich sources of the history of the Jesuits in India in the form of archives of the Society of Jesus, among others, letters and reports they wrote covering their activities and challenges in India.

The strength of the Jesuits, albeit limited success in converting—which was their main aim—in the early modern period, lies in the fact that in order to communicate with the indigenous people about Christianity, they were forced to make immense efforts to learn local languages, wherever they aspired to spread the Gospel. In doing so, they created several notable works in various languages of South Asia. Notable compilations worthy of mention are Miguel d' Almeida's the first known Konkani dictionary, Constantius Beschi's first known Tamil dictionary, Leonardo Cinnami's first known Kannada Malayalam dictionary and Johann Ernst Hanxleden's Sanskrit grammar and dictionary and Xerome Xavier's attempts towards learning Persian.

There are two documented methods in which the Jesuits attempted to convert mainly Hindus, in southern India. This comes to us from studying the Madurai Mission of 1606. Seventeenth century South India has been defined as being "fluid", politically and in matters of religion and society, with various sects of Hinduism, Islam and Christianity co-existing in the segmentary states of Tiruchchirappalli, Tanjavur and Madurai, and each of these various warrior lineages challenged each other in wars and rituals, and for that reason cleared the space for religious innovation as long as it served the interest of conquest, state-building and status enhancement.[5] In comparable circumstances, Italian Roberto Nobili (1577 - 1656) practiced what has come to be known as the "Italian mode" of proselytizing, i.e., of accommodation (*accomodatio*). With his aristocratic approach, and attempts to understanding Tamil culture top-down, considered himself to be a Brahman, i.e, a learned man who had given up material possessions. His argument on the similarity between Christian priests and Hindu Brahmans was reposed linguistically, on the fact 'that they both use a special, difficult to learn, technical and divinely inspired language—Latin and Sanskrit, the Latin of the country'.[6]

In contrast to the top-down approach is the method adopted by Gonçalo Fernandes, who was not only in age and temperament different from Nobili, but their differences in class, education and nationality, probably led to the clashes of opinion on the method of converting. Fernandes had joined the Jesuit order after a brief career as a soldier in the Portuguese *Estado da India* and was by all means it's product. His method of conversion was to disassociate himself from all ways of the pagans and Portugalise them in all matters of life: religion, language, clothing, eating habits etc. With his scant theological knowledge, his only tool could be persuasion, accompanied by economic incentives, rather than theological discussions. His target group, therefore, were the non-elites.

Both European and Indian elite institutions, whether royal courts of the Nayakas or religious schools/ retreats (*matam*), encouraged literary production, the styles and forms of which varied with time, and other aesthetic projects (arts, architecture, etc.), because these were the pillars of their own status evaluation and the constitutive elements of their political legitimacy.[7] Jesuit missionaries endeavoured to appropriate, possess and control the indigenous textual and cultural tradition by compiling dictionaries and grammars, by translating and refuting non-Christian concepts, and by projecting it on a larger European theological and teleological frame. The play of differences, analogies and allegories varied with each and every epistemological move inscribed in the chessboard of time. 'Brahmanical' knowledge, as it came to be regularly defined, would thus resemble, oppose or configure European expectations, depending on political and geographical circumstances, and tropological transformations.[8]

What transpired in the court of Jehangir between his nobles and the Jesuits has recently been brought to light in an extensive article by Muzaffar Alam and Sanjay Subrahmanyam.[9] The authors, using the archives of the Jesuits as well as

Persian records, bring forward a Mughal intellectual who studied the Europeans: Abdus Sattar ibn Qasim Lahauri, who could read Latin and had assisted in the production of a Persian translation of the Bible and complied works such as a summary of Sharaf al-Din Yazdi's *Guzida-yi Zafarnama* (??/ History of Timur), Samrat ul-Falasifa (The Fruits of Philosophers) and *Ahwal-i-Firangistan* (Account of the Land of the Franks) and *Majlis-i Jehangiri* (Assemblies hosted Jehangir, held during the nights where intellectuals were invited to debate over several issues). Sattar's Latin tutors were the Jesuits, in particular Jeronimo Xavier, grand-nephew of Francis Xavier. Sattar's main task in the Mughal administration was to translate European books, not just religious and historical ones, but also others having practical and scientific (*ilmi*) information, as astronomy. Sattar was commissioned to grasp the knowledge that lay locked away in Latin books and Jehangir was interested in knowing if the Jesuits would assist in the setting up of a printing press so that books could be printed in Persian.[10]

The story of the conflict on methods adopted for conversion shows, first and foremost, to a historian interested in learning about transfer, creation, assimilation and diffusion of knowledge, that the Jesuits reached both the elites and the non-elites in the complex Indian social milieu of Hindus, Muslims, Buddhists, Jains, Jews and Armenians. While Nobili, convinced of his "top-down" approach, interacted with the Brahmins, other more ambitions, attempted to convert the Mughal Emperor. While yet others practised piety and attempted conversion, and received some success, among the littoral communities of the Fisheries Coast.

While we have Persian sources to collate what transpired among the Jesuits and the Islamic theologians in Jehangir's court, we have, till now no known sources that will inform us the Brahmins' who once debated with Nobili in the villages around Madurai. We need to know their perpective on the debates. What we know for sure is that the indigenous were not always only interested in Christianity. There was a curiosity about the 'practical knowledge' of the Europeans, specially in the Mughal Court.

China

The year 1583, arrival of Matteo Ricci (利玛窦1552-1610) in Guangdong, marks the beginning of an important phase of Christianity in China. This phase lasted for about two centuries, during which Western science, propagated by the Jesuits, appealed to Chinese intellectuals. He studied mathematics under Christopher Clavius (1537-1612) and was quite knowledgeable in the fields of mathematics and astronomy.[11] Unlike their predecessors, Ricci and his followers realised that the fundamental task for the Jesuits was to counter and communicate with Chinese intellectuals and their cultural heritage. They thus worked hard to learn Chinese language and culture as well as traditions of Chinese learning so that they could engage in a real dialogue with the educated Chinese elites. Their strategies included: studying Confucian classics, adoption of Chinese names and adaptation of Chinese styles of living, clothes, cuisine and even rites and rituals. They also established close contact with Confucian elites and local gentry, introduced Western science and technology, translated Western scientific books and writing into Chinese and published books. For some of these they received the support of the Chinese emperors. Ricci had also won over, in the field of religious belief, many Chinese elites such as Xu Guangqi (baptised in 1611 in Nanjing), Li Zhizao (李之藻1656-1630; baptised in 1610 in Beijing) and Yang Tingyun (杨廷筠1557-1627; baptised in 1611 in Hangzhou). With the help of Xu Guangqi (徐光启1562-1633), a Chinese elite who had converted to Christianity and was the vice-minister of the Board of Rites, Ricci translated six books of Christophorus Clavius' edition of Euclid's Elements into Chinese (*jihe yuanben* 几何原本Elements of Geometry). They were published in 1607. Ricci also translated into Chinese three books on Western astronomy.

Xu Guangqi (徐光启1562-1633) stood at the top of the elite. He was the author of the *Nongzheng quanshu* (农政全书a complete treatise on agricultural administration)[12] and the compiler and translator of the *Taixi Shuifa* (泰西水法Water methods from the West, finished in 1612) written by Jesuit Sabbathinus de Ursis (Xiong Sanba 熊三拔). He became to advocate for 'concrete studies' (*shixue* 实学). (*Shi* 实could be translated into English as solid, practical or concrete.) Subjects such as agricultural administration and water control were regarded by Xu as 'concrete knowledge' that could bring tangible general benefits. Western learning conveyed by the Jesuits was seen by Xu as solid, as the way they produce knowledge could be verified by proper methods. Xu's own work on agricultural administration reflected his experimental attitude towards the accumulation of knowledge. But for Xu, subjects such as agriculture, water control were

---

11 Many of the Jesuits who went to China studied at the Collegio Romano's Academy of Mathematics and the Jesuit College in Coimbra first. See Elman (2005), p.107.

12 The writing of the *Nongzheng* quanshu was a group enterprise, as it was completed, revised and edited by young scholars after Xu's death. See Francesca Bray and Georges Métailié, 'Who was the author of the *Nongzheng quanshu*?', in Jami (ed.) (2001),p. 323.

'useful' because they were relevant to statecraft and could contribute to the welfare of the state and the livelihood of the people (*guoji minsheng* 国计民生).[13]

Translation also played an important role in the transfer of Western science. In order to overcome the difficulties of translation and to facilitate communication, the Jesuits tried to introduce their knowledge by using the classical Chinese terms that were comprehensible by Ming literati (Elman, 2005: 109). The general translation process was that a Jesuit orally translated the Latin texts and dictated it to a Chinese person, who turned it into literary Chinese terms and concepts (Elman, 2005: 111).14 So, the translation work was in fact a cooperative work done by the Jesuits and Chinese literati. Between 1584 and 1790 the Jesuits and their converts in China translated or compiled as many as 437 works in the forms of books, journal articles and manuscripts. While 57% were about Christianity, 30% of the entire publication was concerned with sciences (Elman, 2005: 111).

In the following Qing China, the Kangxi emperor (r. 1662-1722)[15] himself took a great interest in scientific study. He founded a special academy for mathematics and science. In his early reign, he took daily learning on mathematics and astronomy under Jesuit Ferdinand Verbiest (南怀仁1623-1688). The Europeans responded to such patronage enthusiastically. In 1685, Louis XIV dispatched five Jesuits who were also mathematicians including Louis Le Comte (1655-1728) and Joachim Bouvet (白晋1656-1730). Bouvet, for example, stayed in Beijing and taught the Kangxi emperor mathematics and astronomy. The Jesuits' contribution to artillery (for example, cannon making) also met the military needs of the early Qing. Although these Jesuit mathematicians and astronomers gained the favour of the emperor, they gradually disengaged from dialogue with Chinese officials-scholars (Lee, 1991: 11). The Jesuits were also subject to criticism and denouncement from some Chinese nativist scholar-officials, for example, Yang Guangxian (杨光先 1557-1669) attacked Schall for spying and scientific incompetence in 1664.[16] Through the so-called the 'Calendar Controversy' (*lifa zhi zheng* 历法之争), Kangxi supported the service of the Jesuits for the court. In 1692, Kangxi issued an Edict of Toleration permitting the freedom of Jesuit missionaries in China. But the situation changed by the 'Rites Controversy' (*liyi zhi zheng* 礼仪之争) which led to the ban on Christianity in China in 1727.

The sciences served as a lure to the intended propagation of Christianity in China. But the Jesuits did not win as many converts as they expected. The Chinese always drew a distinction between the scientific teaching and the religious teaching by the Jesuits. Fang Yizhi (方以智1611-71) was the first to make this distinction, although he accepted portions of knowledge conveyed by the Jesuits. He said: 'The knowledge from the Far West which entered [China] in the Wan-li period is detailed in 'material investigations' but deficient in speaking of 'comprehending seminal forces' (quoted in Peterson, 1970: 398-399). The distinction drawn by the Chinese was due to a fundamental difference between the Chinese and the Europeans in terms of the views of universe and the Heaven. Confucian scholars served as 'filters' to imported Western science. They were also the medium by which the knowledge got transferred and accepted, albeit after modification or adjustments.

Japan

The Jesuits missionaries arrived in Kagoshima in 1549 when Japan was in the constant military conflicts amongst war lords called daimyo. Anticipating the trade with the Portuguese and Spanish to acquire European muskets and gun powder, local daimyo especially in Kyusyu region enthusiastically patronised the Jesuits missionaries. This promoted the rapid introduction of western techniques such as cannonry, shipbuilding, navigation, mining and metallurgy, which were gradually assimilated by local craftsmen.

As was the case in China and India, the Jesuits' initiative to introduce the western scientific framework was one of the strategies for winning over the Japanese elite for conversion. The Jesuits saw keen interests in natural philosophy amongst the Japanese. Francis Xavier (1506-1552) on his way from Japan to China recommended that the missioners recruited for the Japanese missionaries should not only be "philosophers… well trained in dialectic but also well trained with cosmic phenomena because the Japanese are enthusiastic about listening to explanations of planetary motions, solar eclipses, and the waxing and waning of the moon. All explanations of natural philosophy greatly engage that people's

---

[13] On Xu Guangqi, see e.g., Jami (ed.) (2001).

[14] This method was also adopted after 1850 by Protestant missionaries and their collaborators in their translation of works of modern science primarily from English into classical Chinese. See Elman (2005), p.111.

[15] The most common way of referring to a Chinese emperor since the Ming dynasty is by his reign-title (*nianhao* 年号) rather than by his given name. The term 'Kangxi' is a reign-title rather than a name.

[16] Schall proved innocent of the accusation for scientific incompetence with the help of Jesuit Verbiest but other charges were never dropped. See Zurndorfer (2009), p.89.

minds"[17] Alessandro Valignano (1539-1606) also reported the keen interest in scientific knowledge such as geography and astronomy in Japan, and urged the Society of Jesuits to send more qualified missioners. Valignano was the founder of the Jesuits education institutions in Japan. The institutions consisted of seminario for primary schooling[18], noviciaso for secondary education and collegio in Funai located in Funai for further priesthood training. The curriculum of *collegio* reflected the Aristotelian doctrines of late medieval scholasticism, and included theology, philosophy, canon law, jurisprudence, logic, natural science, rhetoric and music.[19] The collegio served also as research institution of the Japanese language and culture: three Portuguese-Japanese dictionaries were published by the Jesuits and used in preparing printed translations of many Western and Japanese literatures for evangelical purpose.

Such Jesuits initiative did win Christian converts amongst Kyusyu daimyo. Notable Christian daimyo included Otomo Sorin (大友宗麟1530-1587) and Takayama Ukon (高山右近1552-1615)[20]. Oda Nobunaga(織田信長1534-1582), the most powerful warlord, also favoured them in order to counteract the aggressive Buddhist rebellions. However, it is important to note that, unlike the case in China and India where the Jesuits interacted with intellectual court elites to produce translations of scientific works, their brotherhoods in Japan operated under the protection by provincial daimyo, and their influence was limited in the cultural and intellectual capital of Kyoto.[21]

It is also fair to say that political conditions rendered the knowledge transfer of the Jesuits science to Japan largely incomplete. After the death of Oda Nobunaga, his successor, Toyotomi Hideyoshi (豊臣秀吉1537-1598) began to eliminate the Christian influence from Japan. Under the Tokugawa regime from the unification in 1603, the Tokugawa government made it clear that Christian faith was officially banned through a series of missionary expels and the execution of the converts in the 1630s.. In 1639, the government prohibited European nationals from entering the country except for the employee of the Dutch East India Company and also prohibited Japanese nationals from travelling abroad. Thus the Jesuits involvement in Japan lasted less than a century and it was confined to a limited part of the country. The strict suppression of the faith under the Tokugawa regime – underground followers were executed – made it difficult for the Jesuit knowledge to leave a systematic influence.

Nonetheless, the legacy of the Jesuits knowledge remained. Nagasaki became a repository of European scientific knowledge during the Tokugawa period. A group of Nagasaki interpreters kept the legacy of European knowledge and the imported Chinese translations of the Jesuits texts came through its port. The latest European knowledge of astronomy and medicine were introduced in Nagasaki through books and the Dutch East India Company officials. Scientifically minded physicians and scholars were attracted to Nagasaki from across the country to learn European knowledge. They gradually came to form the intellectual group of Dutch Learning by the mid eighteenth century, which played an important role in Japan's adaptation of Western science and technology in the nineteenth century.

Conclusion

Mughal India, late Ming and early Qing China, and Tokugawa Japan were as keen to access knowledge from the Europeans as the later were to gather information of the "exotic". The Jesuit then became an important conduit for the transfer of knowledge and their works present to us an opportunity to compare the diverse cultures on China, Japan and India. However, what the Jesuits transferred was not just science and technology but also a new way of teaching and learning coming from a different cultural context. The patterns of intellectual interactions and knowledge transfer were determined by cultural regimes which shaped the mentality of elites who either promote or restrain the generation and diffusion of 'useful knowledge'. Different kinds of elites had different definitions of 'useful knowledge' and ways of appropriating Western knowledge because of their cosmological orientations and intellectual traditions.

Abstract

The introduction of laboratory education at Belgian secondary schools during the years 1880-1914 was strongly influenced by German science education. A large part of school books and textbooks used by Belgian science teachers were translations of German publications and the laboratory apparatus in Belgian school laboratories was to a great extent of German origin. Belgian academic scientists got acquainted with German science education combining research and instruction during post-academic training at German universities and laboratories. Fascinated by the integration of experimental and instrument manipulations in German science education, they also ardently pleaded for the introduction of laboratory instruction at secondary schools, created from 1880 onwards at state schools. My paper deals with the characteristics of Belgian experimental education as well. This will lead to an analysis of the uniqueness of Belgian science education at secondary schools, also influenced by French science, illustrated by the following quote of a Belgian scholar concerning disseminating science: 'Belgium is surprisingly well placed to serve as mediator between different nations.'

Introduction

The study of science education also includes experimental instruction: scholarly attention for experiment in science education has risen during the last decade and 'learning by doing' as research topic recently increased in significance, not only in historical studies on popular science books and periodicals promoting a homemade science and on the distribution and the use of experimental kits, but also in education.[1] This paper on the implementation of laboratory instruction in the courses of chemistry and physics at Belgian secondary state schools at the end of the 19th century, aims on the one hand at being supplementary to former studies in national historiography rather emphasizing on institutional aspects (the history of schools, the evolution of educational laws) or on social studies of the target groups of 19th-century education. On the other hand, the pursuit of this paper is also to be complementary to the existing international historiography on secondary science education by explaining the characteristics of the Belgian case.

Because of its central geographical position in Western Europe, Belgium was pre-eminently a country of intellectual exchange, already agreed upon by the 19th-century contemporary actors as well. Belgian intellectuals promoted the idea of an 'international patriotism'; the nation's national individuality was precisely to be found in being international.[2] This was also the case for the circulation of science: Belgium was influenced by several different scientific cultures, especially by neighbouring countries France and Germany, the two leading scientific centres in the 19th century, and Belgian scientists coquetted with the idea that Belgium functioned as a country of intellectual passage, both for the production of knowledge in a scientific, rather closed area and for the communication of science in the public sphere. That did not alter the fact that 19th-century public discourse on science and science education mainly took Germany with its first-rate position in science and education as the standard.

Consequently, the aim of this paper is to find an answer to the question: to what extent Belgian laboratory instruction in secondary education meant for the elite and the upper middle classes, was influenced by foreign and in particular German educational and scientific cultures. This paper deals with secondary education, since natural sciences definitively got embedded in the curricula of secondary state education from the beginning of the years 1880 onwards, in contrast with Belgian primary education wherein mandatory courses in natural sciences were removed by catholic politicians. My investigation on laboratory research in secondary state education in Belgium is based on textbooks, brochures, official inspection reports and hand written accounts of teachers' meetings at state schools.

International or nationalistic character of science at Belgian secondary schools?

Secondary state education in Belgium was reformed during the liberal government by means of the law of 1 June 1850, providing for the establishment of ten Royal State Schools ('Athénées Royaux'), one in each provincial capital (Brussels, Antwerp, Ghent, Bruges, Hasselt, Liege, Mons, Namur, Arlon), plus Tournai. These state schools were public, secular institutions - although religion education remained a permanent issue of debate, particularly under catholic government - and they had a propaedeutical function for university education.

Belgian teachers were aware of developments and debates in foreign science education, for instance on the contribution of mathematics in physics and the debate on physics as an experimental science. Belgian official inspection reports explicitly referred to current developments (reforms, laws) in secondary education in neighbouring countries (Germany, France, The Netherlands and Great-Britain): developments in Belgian education were usually compared to these different nations and Belgian secondary education was embedded in an international context.[3] Belgian politicians were longing to copy the German structure of secondary education at the Belgian Royal State Schools: the German 'Gymnasium', a grammar school with a curriculum based on ancient languages was comparable to the Humanities section, 'Realschulen' (modern schools with scientific and technical objective and without Latin instruction), teaching science and preparing higher education at the 'technische Hochschulen' and the 'Höhere Bürgerschule', comparable to the professional section of the Belgian Royal State Schools.[4] Belgian architects drew inspiration from study trips to German secondary schools for the construction and the infrastructure of Belgian secondary schools. Following the German debate, in Belgium too the creation of practical science lessons at secondary schools threw doubt upon the ideal of classical education.

Furthermore, the admiration for German science education was mirrored in Belgian educational scientific collections. Belgian school laboratories usually possessed a large number of scientific instruments produced in Germany, 'in which one

can have absolute trust',[5] amongst others spectroscopes and polarimeters of the company Franz Schmidt & Haensch (Berlin) well-known for its optical instruments, or microscopes of Carl Zeiss (Jena).[6] German scientific apparatus were promoted in Belgian textbooks too; Jean Chalon wrote: 'The Berlin Company Klönne & Müller also offers a large number of microscopic preparations, beautiful and not expensive.'[7] Moreover, the use of (translated) German textbooks was usual. These books could also be found in school libraries, amongst others translations into French such as R. Fresenius' 'Traité d'analyse chimique qualitative', of Justus von Liebig's 'Traité de chimie organique' or F. Mohr's, 'Traité d'analyse chimique' (1888).[8]

However, this German influence in Belgian secondary science education did not exclude admiration for other foreign traditions. Moreover, the fact that Belgian secondary science underwent strong influences from abroad appeared to be an essential characteristic of national education. School libraries for instance also contained British and Dutch textbooks on experimental chemistry and physics. Belgian education was importantly influenced by French secondary education too, the French textbook of Adolphe Ganot's *Traité élémentaire de physique expérimentale et appliquée* (1851) and its later editions was used as official pedagogical material at Belgian Royal State schools and Teachers' Colleges. Ganot's physics textbook was largely distributed in the 19th century, amongst others in Great Britain,[9] but also in neighbouring country Belgium, where French was the communication language in all state schools.

The provision of textbooks changed over time, and if initially it was based mainly on (German and French) imports, subsequently they were replaced by textbooks written by Belgian authors (both teachers and academic scientists). Yet these textbooks on physics remained often inspired by textbooks such as those by Ganot: the illustrations in Ganot's textbooks were sometimes adopted or comparative references were publicly made to his book implying that it remained the standard.[10] Belgian textbooks had to follow the official educational programs and they had to meet other criterions as well: in regard with the lay-out, textbooks had to contain illustrations large enough to give pupils a pleasant impression. Concerning the content, a clear and succinct style on a basic level geared at young pupils was considered important just as an accurate description of phenomena, definitions, laws and experiments.[11] Some of these Belgian textbooks were approved by the Ministry of Education to be used as official textbook in state secondary education, amongst others 'Lecture on basic chemistry' ('Traité de chimie élémentaire') written by L. Michelet, doctor in physics and mathematics and teaching at the state Teachers' College of Brussels. His later published textbook 'Lecture on elementary physics meant for Teachers' Colleges and secondary schools' ('Traité de physique élémentaire à l'usage des écoles normales et des établissements d'enseignement moyen') would replace Ganot's textbook at Belgian Royal State Schools and Teachers' Colleges, for instance at the Ghent Teachers' College for state secondary education of inferior level from 1888-1889 onwards.[12] Other textbooks were used as national substitute for Ganot's textbook as well, such as 'Elements of physics meant for state secondary schools' ('Eléments de physique à l'usage des écoles moyennes') written by J. Fleury, teacher at the Royal State School of Liege or 'Lecture on elementary physics' ('Traité de physique élémentaire') written by Fleury and G. Duguet, repetitor at the Mining School of Liege. The latter was divided into two parts: the first part was devoted to the general characteristics of matter and the theory of heat, whilst the second part treated on acoustics, optics, magnetism and electricity. Every chapter ended with a number of exercises. This textbook also paid attention to new scientific discoveries and its applications and to the current status of modern science.

Remarkably enough, the aforementioned Belgian textbooks were not applied as instruments of patriotic education or as a means to pay a heroic homage to national scientists. The canon of scientists quoted in these textbooks remained international (e.g. Torricelli, Pascal, Regnault, Gay-Lussac, Otto de Guéricke, von Helmholtz).[13] The fact that secondary science education was not striving explicitly for nationalistic aspirations can also be illustrated by two meetings of the entire teaching staff of the Royal State School of Tournai around the turn of the century. Debates took place on the questions on how and to what extent teachers of general courses in their respective fields could contribute to education in 'national pride' and on whether or not pupils of secondary schools had to be instructed in a more systematic manner about the contribution of Belgium in the progress of the arts, literature, industry and of the sciences. The teachers in natural sciences and

mathematics decided unanimously that the contribution of Belgian scientists to scientific progress had to be explained to the pupils on a mere occasional basis. Indeed, biographies of Belgian scientists and explanations on the nature and the importance of their research could be explained at the right moment and on the right tone, geared at the pupils' level and without a sterile and pompous rhetoric. They added that only a few compatriots were prominent scientists.[14]

Experimental instruction and the implementation of school laboratories

Belgian secondary education was strongly orientated towards academic instruction, probably due to the fact that most of the teachers in chemistry and physics for secondary education on a superior level were academically trained and thus familiar with academic experimental education. As a result laboratory courses at secondary schools were inspired by academic experimental training. Experimental instruction at Belgian universities was in its turn following the example of German academic tradition, fiercely admired by Belgian scientists for its independent research done by students, its mandatory composition of a dissertation and its development of experimental research. Belgian scientists commended on the large investments of German universities into libraries, scientific collections and laboratories for chemistry, physics, physiology and anatomy. In the years 1860-1880 Belgian academic scientists were zealous advocates of the establishment of similar practical courses at faculties for Medicine and Sciences in order to introduce young students to scientific apparatus and research practice, resulting in a voted bill in 1890, explicitly encouraging the Belgian universities to orientate themselves towards research and to adopt seminars and practical teaching methods.[15]

Following these developments of the institutionalization and professionalization of natural sciences at universities installing practical seminaries and laboratories according to the German example from the years 1870 onwards, politicians, scientists and teachers pleaded for the establishment of experimental instruction at secondary schools as a substitute for the existing dogmatic and ex cathedra-education in natural sciences. Furthermore, the emancipation and professionalization of chemistry and physics in secondary science education curriculum required appropriate classrooms and didactic material. A Ministerial Order of 15 January 1880 summoned a commission of school inspectors and teachers to propose measures for the development of suitable infrastructure and didactical collections meant for science education based on observation and manipulation in the Royal State Schools, secondary state schools and the state Teachers' Colleges. In 1881 the government granted an allowance to the aforementioned institutions meant for the purchase of physics instruments.[16] Moreover, separate classrooms for the courses of physics and chemistry were provided. At the end of the years 1880 official inspection reports mentioned that most of the Royal State Schools had the disposal of both a cabinet of physics and a chemistry laboratory in order to support theoretic science lessons with experiments and manipulations, financed by both state and local authorities.

The Royal State School of Brussels for instance had chemistry and physics laboratories at its disposal from 1887 onwards; these science classrooms were financed by the city council. The physics laboratory and its adjacent physics auditorium were established on the initiative of Max Seligmann, teacher in physics at this school. Glass cases contained a large collection of instruments suitable for conducting experiments.[17] The chemistry laboratory of the Brussels Royal State School, its chemistry auditorium, library and room of balances, was known as an exemplary institution. It was equipped with six cages for evaporation, a steamer, a drying kiln and two sinks and amongst the scientific instruments were microscopes, objectives, stereoscopes, polarimeters, saccharimeters, spectroscopes, Bunsen burners, voltameters, small and large Ruhmkorff coils and apparatus for the manipulation of gases, including a gasometer of Gay-Lussac with a capacity of 36 litres.[18]

This chemistry laboratory was arranged according to the guidelines of Charles-Polydore Francotte (1851-1916), doctor in natural sciences at the Liege State University, teacher at the Royal State Schools of Namur and Brussels and from 1890 onwards lecturer and professor at the Free University of Brussels ('Université Libre de Bruxelles') holding the chair in animal embryology.[19] He excelled in experimental secondary science education by performing experiments and demonstrations and he emphasized the characteristic properties of secondary science education. Emphasizing the

characteristic properties of secondary science education, Francotte excluded the installation of imitations of academic laboratories at secondary schools. He stressed that in contrast with academic laboratories meant for experimental instruction where students could work without constant supervision, school laboratories meant for young pupils unfamiliar with scientific manipulations had to be arranged differently for reasons of safety. The chemistry teacher had to supervise actively and continuously his pupils in order to avoid accidents. Authors of textbooks warned as well for the dangers of experimental training: 'In novice hands the first chemistry manipulations might result into serious, even mortal, accidents.'[20] Thereby, school laboratories had to be installed so that the teacher could oversee the entire class all the time. Therefore Francotte equipped his laboratory with four different manipulation tables with each a series of instruments and reagents and each table was meant for a group of four pupils.[21] Moreover, Francotte insisted on the huge importance of hygiene and ventilation in school laboratories: harmful gases had to be evacuated in a safe way. The arrangement of equipment implied precautionary measures by placing the cages of evaporation in the middle of the laboratory - in connection with windpipes reaching the ceiling - instead of against the walls. Pupils were only allowed to exercise with some of the laboratory equipment: in the Royal State School of Brussels for instance the room of balances contained several expensive balances, yet pupils had to practise with a cheaper specimen before they were allowed to use the more expensive ones.[22] Furthermore, teachers also argued on the necessity of the installation of ateliers where pupils could construct themselves scientific instruments, which already existed at Teachers' Colleges.[23]

The importance of laboratory instruction for the chemistry and physics courses instead of abstract, theoretical and memory-based science education was also stressed at the state Teachers' Colleges. Their educational program of 1881 stated that 'The education of natural sciences has to be based on observation and experimentation.' Teachers' Colleges for secondary education of both the inferior and the superior level paid attention to experimental education in the courses of chemistry and physics, learning future teachers how to use microscopes and to describe, explain and perform experiments for secondary education pupils.[24] Notwithstanding the fact that observation, manipulation (measuring and weighing of objects) and experimentation were promoted as the appropriate pedagogical method for the instruction of chemistry and physics, teachers agreed that memory work still had its place and they determined exactly what had to be memorized: formulae in physics had to be learned by heart just as the chemical and physical composition of solids in chemistry, but - again - experiments could stimulate and even guarantee remembering these definitions.[25]

Next to experiments, agreement existed on the importance of the inductive method in secondary science education, not only in chemistry, but also in physics. Teachers mentioned that the use of the deductive method in the instruction of physics did not teach anything new to the pupils, since the experiment executed by the teacher was diverting and only illustrating and affirming the aforementioned explained laws and theories, whilst the inductive method allowed the pupils to explain and to understand the observed phenomena in a heuristic and self-reliant way.[26] It was obvious that chemistry was suitable for experimental instruction, but teachers also insisted that physics was a pre-eminently experimental science, notwithstanding the fact that it was based on mathematical formulae and axioms. Following the tendencies of French and German education where the merely mathematical approach of physics lost ground in secondary education,[27] teaching staffs at Belgian secondary state schools discussed the contribution of mathematics in physics. Marcellin Chapaux, teacher in natural sciences at the Royal State School of Tournai, put forward that physics instruction had to offer insight in the natural phenomena and its laws and that physics 'was an experimental science above all.'[28]

Conclusion

The admiration in Belgium for foreign traditions of secondary education was not only purely rhetorical though. Moreover, the fact that Belgian secondary science education underwent strong influences of Germany and France, appeared to be an essential characteristic of the national style of secondary education. Contemporaries agreed that Belgium was a country of intellectual passage and that Belgian secondary science education was situated in a transnational context. Internationalism was cultivated; Belgian education considered itself being appropriate to serve as mediator between different nations, according to a contemporary scholar: 'Why not draw abundantly from these [foreign] sources of education? (…) Within this context Belgium is surprisingly well placed to serve as mediator between different nations.'[29] The use of German and French textbooks and the promotion of an international canon of scientists in Belgian textbooks implicated the uncomplicated integration of 'foreign' patriotism in Belgian state secondary education. The explicit longing for the German laboratory courses (mainly at the Realschule) - traces of the German influence are to find in school infrastructure, laboratory apparatus, textbooks and inspection reports - followed the Belgian academic tradition.

Abstract:

Recently, several papers in the field of science education have been published that analyse school and university textbooks with respect to accounts of certain historical experiments, such as Millikan's oil drop experiment or the photoelectric effect. In doing so, the authors generally criticize the accounts in today's textbooks as erroneous with respect to the historical experiment, as well as misleading with respect to aspects of the nature of science. Even though these criticisms are well founded, it remains an open question why these accounts can be found in textbooks. It appears to be evident that not every detail of the historical experiment can be included in the description; consequently, decisions are to be made on which aspects are relevant and which are superfluous. These decisions are not simply made, but are the outcome of a historical process –consequently it appeared to be interesting to examine the genesis of these descriptions.

Introduction

One might expect that educators who are advocating the use of history of science are happy when historical aspects or historical experiments enter science textbooks for schools. However, in several cases they are not. There are a number of reasons why this could be observed: There are some examples where history of science is still reduced to names and dates or used in a purely anecdotal manner. However, references to historical experiments should be an indication of a more adequate use, particularly when they go beyond giving a date and a name. Yet, things are not that easy, and experimental accounts may also turn out to be problematic. In this respect, at least three main reasons can be identified: The story is inadequate from a scientific perspective. As we are discussing only science textbooks and not history textbooks, it should probably be extremely exceptional. However, having such a mistake is of course extremely problematic as the authors should be expected to get at least this part correct. However, taking a closer look at historians' accounts of experiments reveals problems can occur in this respect with peripheral instrumentation or procedures. In this respect it is important to keep in mind that also science museums as well as historical accounts of experiments focus on what is considered to be the central unit of a device. Consequently, one should not be surprised that textbooks have a similar attitude as space is limited and thus considered to be precious. However, when judging these aspects, one has to keep in mind that it is not that obvious where an adequate simplification is made or whether something is already a misinterpretation. In any case, such accounts may lead to an oversimplification of experimental practices and could thus be misleading.

The story is inadequate from a historical perspective. This is certainly not that unlikely, and here criterions are also not that simple. Whilst misdating, misplacing or giving wrong names is fairly obviously erroneous, one could (and should) ask where an account of a historical experiment can still be considered as historical, and even more, as adequate from a historical perspective. Obviously, a science textbook is not able to give all the details about instrument makers, financial background, social interactions, philosophical beliefs of the main actors, etc. Whilst one cannot expect every detail to be included in a science textbook account, at least central historical aspects should be mentioned in order to take this as an account of an historical experiment.

One might expect that these are the central levels of misrepresentation of historical experiments; however, there is at least one more. The story might also be inadequate from a nature of science point of view. History of science is strongly advocated to enable students to develop a better understanding of the nature of science. Consequently, an account of a historical event (which could be an experiment) should support an understanding of the nature of science that is considered to be adequate.

From the perspective of a historian, one could and should ask how these stories about historical experiments came into the textbooks. Obviously, accounts on experiments in science education are nothing stable or constant, thus one might expect that accounts of historical experiments we find nowadays in modern textbooks are the outcome of a historical process of textbook writing.

This process may reflect different aspects: of course, textbooks reflect what is considered to be accepted knowledge, even though in the early 19th century, textbooks were also a means to communicate new knowledge. But there are also different aspects on what education should achieve, consequently different (aspects of) historical episodes may be considered as being relevant for the intentions of the textbook authors. This is not limited to explicit intentions which can be found in an exemplary manner in textbooks published during German fascism. There are also implicit intentions and beliefs that may play a role with respect to what historical episodes should by exemplified. And of course one has to consider the changing role of textbooks, consequently, accounts may be modified due to changes in the educational concept and the role textbooks have in this respect.

However, when taking a closer look at accounts of historical experiments, some aspects appear that seem to go beyond the individual cases. In the following, we will discuss three examples and finally are going to draw some more general conclusions.

The speed of light and Ole Rømer

Ole Rømer is frequently mentioned as the first person to measure the speed of light. In 1676, a short account on his work was published in the Paris Memoires de l'Académie Royale des Sciences. In this account, it was mentioned that Rømer aimed to related measurements of Brahe made at Uraniborg to those made in Paris (see Bobis & Lequeux 2008). Rømer observed a discrepancy between the time the moon Io vanished behind Jupiter (or in the shadow of Jupiter) and the time calculated from the period of Io's revolutions around Jupiter. When the Earth was moving away from Jupiter, the moon vanished somewhat later than calculated, when the Earth reduced the distance to Jupiter, the moon was too early. Rømer explained this discrepancy by arguing that the light needs some time to travel the additional distance between the two planets.

This observation is a classical example of an historical experiment that is found in many textbooks. However, as Wallasch already observed almost thirty years ago, these accounts are erroneous in several aspects: Remarkably enough, he even identifies several scientific mistakes in the accounts, to mention but one very striking: It is indicated that the vanishing of Io behind Jupiter is belated some 22 minutes with respect to the diameter of the orbit of the Earth. This is clarified by arguing that when the observation is made at C (see Fig. 1) and half a year later at A, the delay is accumulated to 22 minutes.

A central problem with this line of argumentation is the assumption that Io (and Jupiter) can be observed whilst being behind the sun – everyone who has ever tried to look 'through' the sun is well aware that this is pure nonsense.

Remarkably, Wallasch's paper seems to have had next to no impact on textbook authors, this description and the corresponding diagram is still to be found in most textbooks. Moreover, most textbooks that mention Rømer's work claim that he measured the speed of light. This is not what he did, nor did he have the intention. He wanted to compare data that were taken at two different observatories (by Cassini and Brahe) and thus tried to connect the times of observation through Io as a 'celestial clock'. And finally, the impression is created that Rømer's work was straightforward but not very accurate, most books mention a value of 220.000 km/s as a result of his 'measurement'.

To summarize it can be argued that the description of Rømer's work on the observations of Io is misleading in the scientific as well as in the historical and the nature of science perspective. At the same time it gets evident that such an approach has some stability even when it is criticized.

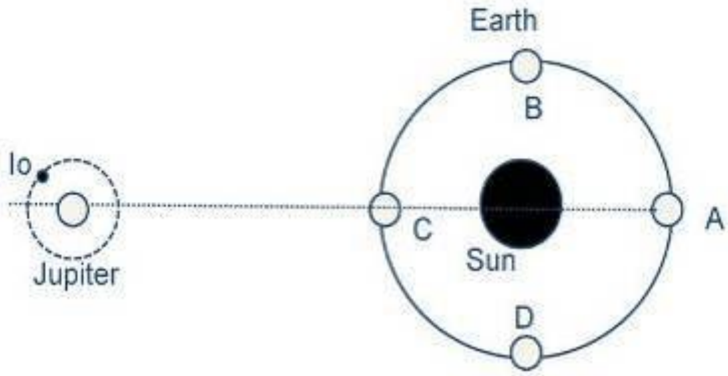

Fig. 1: Principal illustration of Rømer's observation (erroneous).

Millikan's oil drop experiment

Millikan's oil drop experiment to determine the elementary electrical charge is among the classical experiments from the history of physics. Actually, according to a non-representative survey among physicists, it is considered to be among the 'most beautiful' experiments of all time (Crease 2002). And of course the description of the experiment is found in almost every modern textbook for upper secondary school physics teaching. However, when looking a little bit more closely at these accounts, it gets evident that these descriptions are not really satisfying. As Niaz observed, "[m]ost textbooks do not present Millikan's oil drop experiment within a historical, much less philosophy." (Niaz 2000, 503, see also Rodriguez & Niaz 2004, and Niaz & Rodriguez 2005).

However, this criticism addresses modern textbooks. Niaz did not analyze historical textbooks or the genesis of these accounts.[1] When looking at the introduction and subsequent treatment of this experiment in German physics textbooks, some surprising details appear. The first description in a German school textbook can be found already in 1915 (Püning 1915). This description is remarkably clear and adequate, the working principle of the experiment is adequately reproduced and some details are given. However, this description is an exception, most textbooks until the 1950s do not mention Millikan or the oil drop experiment. Only then, it becomes a standard experiment in the context of physics teaching. In most of the textbooks, the experiment is placed in the context of the introduction of the elementary charge, it appears to be simple, straightforward, and its result unambiguous (which is not the case when the controversy between Millikan and Ehrenhaft is taken into consideration, see Holton 1981). Yet, it is not only the misleading description of the status of the experiment that has to be criticized. Actually, the procedures as described in many accounts do not represent the ones by Millikan; particularly the determination of the oil drop diameter is described in a manner that does not work. Moreover, several accounts describe a method where the oil drop is made to levitate due to the electrical field that is compensating the gravitational force. Even though Millikan initially tried this kind of procedure, he quickly realized that he had to modify the experiment as Brownian motion made it next to impossible to be sure that the oil drop was at rest.

When comparing different accounts, it gets evident that the description of the experiment is modified towards the modern account. This can be described as being an idealized version of the initial working principle. In some sense, the historical experiment is more and more transformed into an ideal of this experiment that shows even some resemblance with a computer simulation. This detail is also strengthened by the illustrations: Initially, there are sketches of the working principle, in the 1970s, photos of the standard school version of the experiment are included, whilst in the most recent books schematic illustrations are used that resemble a simulation and in particular does not provide any realistic impression of the dimensions of the experiment and the oil drops.

[1] Such an analysis has been carried out by Parlow, her results are discussed in Parlow & Heering (2009).

The example of the electron

For the analysis of the portrayal of electrons in schoolbooks 22 schoolbooks with publication dates from 1905 until 1950 were examined. The electron usually appeared in four different contexts, these being the nature of the cathode rays, of electricity, of the atom and of the electrolysis process. The results of the analysis that can be categorized are summarized here.

For almost every books the authors assume a position of conclusive authority when writing about the electron. Although it is noted in many cases that the respective theory is just that, a theory, most authors do not mention past failures in the search for answers, competing theories or possible future developments. They almost never mention the people behind a theory or important experiment and their struggles in their search for answers. And if they ever do, it is only with a delay of several years. Experiments are simplified into ideal representations of the actual real process with all its complications. This idealized arrangement of facts leaves the reader with still lifes of the actual historical process of scientific progress.

In 1897 Thomson formulated that the cathode rays are negative particles with a certain relation of charge and mass. In 1899 he could show that the particles found through thermionic emission and photo emission possess the same relation of mass and charge. In 1906 he was awarded the Noble Prize for his works regarding the electron. The cathode rays are mentioned for the first time in the schoolbook *Grundriß der Physik* by Spies from 1913. However, Thomson's name is never mentioned in any of the books.

Drude, who proposed the model of the electron gas to explain the electric current in 1900, and Tolman, who could produce experimental evidence for this concept in 1916, are not mentioned in the schoolbooks as well, although in their work, the electrons are directly connected with the conduction of electricity for the first time in the schoolbook *Lehrbuch der Physik* by Püning from 1915. The core facts of Drude's theory are still mentioned as late as in 1947 in Speitkamp's *Lehrbuch der Physik*.

The planetary model of the atom is mentioned for the first time in Meyer's *Physik und Chemie* from 1926, twelve years after Rutherford's discovery, who, again, is not mentioned by name. However, Bohr is mentioned but the most important details of his model are not, there is no difference to the planetary model of the atom. De Broglie's matter waves are not mentioned at all, although Davidson and Germer could demonstrate in 1927 the ability of the electron to behave like a matter wave.

A notable exception to this portrayal of the scientists related to the electron is the way Millikan is depicted. Schauff sings his praise when he writes in his *Grimsehl Lehrbuch der Physik* from 1928 that of all the attempts to measure the charge of the electron the most precise was Millikan's through and exhaustive oil drop experiment. However, as we have discussed already in the previous section, the accounts on Millikan's work until after World War II are few.

Just as people and controversies behind a theory or discovery are almost never mentioned, so are the experiments. This is particularly striking with respect to the methods of measuring the electron charge. Descriptions in the schoolbooks can be seen as being reduced into idealized versions of the experiments. They are stripped from their historical contexts and significantly simplified. As a result of these modifications, they appear as simple devices that only exist to prove a point. In his *Grimsehl Lehrbuch der Physik* Schauff even goes as far as to arrange the different topics relating to the electron, theories and experiments, in such a way as that they lead to the planetary model of the electron. Here the reader finds a remarkably idealized medial reproduction of the scientific process and, as part of that, a line of argumentation that doesn't have much to do with the actual historical process. However, at the same time the author is creating the impression of historical (as well as scientific) accuracy and correctness. Schauff does mention Millikan but for his arrangement of topics this doesn't matter because he describes a method for measuring the charge of the electron that is derived from electrolysis.

Schauff's book is certainly an extreme example, but almost all books under examination show this tendency to create still lifes of the scientific process and to assume an authoritarian tone by re-creating the physics of the electron on their pages.

However, when analysing the books one after the other it gets obvious that the concept of the electron changed significantly over time and from book to book. Over time, when it comes to the question whether positive electrons exist and from book to book regarding the question whether the electron is a particle with a mass or a quantisation of charge or both.

Positive electrons are mentioned for the first time in the schoolbook *Anfangsgründe der Physik* by Knops from 1906. He states that the elementary charge is composed of positive and negative electrons. Positive electrons appear in some of the books until they are doubted for the first time in Püning's *Lehrbuch der Physik* from 1915. "If one would assume according to Symmer two fluids, but only one being movable, the other fixed to the matter, this would correspond to Franklin's hypothesis. The movability of negative electricity is out of question. As one assumes nowadays, the fluids, at least the negative one, are purely composed of identical small particles, the so-called electrons". (Püning, 1915). His book is in several respects remarkable (as already mentioned in the analysis of the accounts on Millikan's experiment). Here, he seems to indicate that electrons are a hypothesis, he also creates the impression that there are still open questions (e.g. with respect to the positive charge), and he is making adequate historical references, thus putting the actual theory in a historical perspective. However, Püning also makes conflicting statements about the electron. In the contexts of electricity and electrolysis they are postulated but in the context of the cathode rays Püning doubts their existence. After 1915 positive electrons do not appear again in the context of electricity but are used in Meyer's *Physik and Chemie* from 1926 in order to explain the structure of the atom. Meyer argues that negative electrons float around a core that is mainly made up of positive electrons. They are mentioned still in another book in the context of the atom. In Schauff's *Grimsehl Lehrbuch der Physik* from 1928 there is already only an ambiguous statement about positive electrons in the context of the atom. He describes that some of the electrons might be build into the atomic nucleus. In Schippenkötters *Physik für höhere Lehranstalten* from 1931 the protons are mentioned for the first time. Schippenköter also describes a negative charge as an abundance of electrons and a negative charge as a lack of electrons. From then on, positive electrons are not mentioned anymore.

From this brief description it gets evident that the concept of positive electron changed its meaning at least twice. First, positive and negative electrons appear in order to explain positive and negative electric charges. Afterwards, positive electrons are no longer used to explain positive charges –they reappear in the context of the atom. They are now used to explain the positive charge of the atomic nucleus. Finally, there is the transition to our understanding of electric charge and the atom. In both cases the positive electron was first postulated, the concept was then weakened by ambiguous or conflicting statements and then replaced by a newer one. However, in each individual instance, the respective understanding is depicted as a 'fact'.

The question whether the electron is a quantisation of charge or a particle with mass or a particle that carries an elementary charge remains unsolved until the 1950s. For Knops the electron is clearly a charge quantisation when he writes in 1906 that the elementary charge is an electricity atom which is called electron: "One looks at these electrical elementary quantities as electrical atoms and names them electron (positive and negative electron)" (Knops, 1906). In Weiler's *Elektrizität und Magnetismus* from 1905 the author writes that the smallest particles with mass are the electrons to which the elementary charge is connected: "The smallest mass particles which are connected to the electrical elementary quanta are the electrons …" (Weiler 1905). In Günther's *Grundriß der Physik* from 1942 the author remains ambiguous on the question when he first writes that the negative electric charge, just like matter, is composed of atoms of electricity, called electrons, while in a later chapter he states that the electron is a particle with mass. These three ways of describing the nature of the electron change from book to book, with no recognizable pattern. The fraction describing the electron as a particle is the largest, with 13 books doing so. In three books the electron is described as a quantisation of charge and six books remain unclear on that matter.

Conclusions

It should be understood that this paper forms very much a workshop report, there appears to be more potential in schoolbook analysis than the details we have been able to discuss. Yet, some generalizations appear to be possible even despite this limitation. First of all, evidently the analysis of textbooks can help to develop an understanding of how accounts of (historical) knowledge production were created. This is on the one hand relevant to historians of science as our modern understanding of historical experiments is frequently shaped initially through these textbooks – this is the first contact with historical experimentation for future historians of science. Moreover, these accounts may help to clarify to a certain extent open questions with respect to theory development. Examples such as the discussion of the electrons show that they initially were more a theoretical entity than a real object. In this respect, school science textbooks seem to have developed towards a more positivistic (and maybe simplistic) position. Yet, another interpretation appears to be possible: The characterization of electrons as hypothetical particles can be taken as an indication of this aspect being still an open question among scientists. Thus, textbook descriptions can be seen as an indication of acceptance of certain issues that had been previously discussed controversially.[2]

At the same time, such a textbook analysis can be relevant for didacticians: these accounts may help to develop an understanding of the genesis of the accounts that are to be found in today's textbooks. This is on the one hand relevant for the perspective of future teachers on materials available to them. Such an analysis may enable them to develop a more critical perspective on recent textbooks. They can realize that these accounts are not necessarily the only possible way to describe scientific facts and their development. On the other hand, particularly the problematic aspects in the accounts of the historical development may cause difficulties in the acceptance and use of the history of science in science education. Again, this appears to be relevant as this is the first source science teachers have when they intend to use historical aspects in their teaching.

And finally, such an analysis may help to identify mechanisms that lead to a positivistic tone in modern textbooks by showing the increasing decontextualisation of the texts.

---

[2] Such a claim cannot be made for the eighteenth and nineteenth centuries, at least university textbooks in these periods were also used to communicate new knowledge.

VISUAL AIDS IN *THE NINE CHAPTERS ON THE MATHEMATICAL ART*: CONNECTIONS BETWEEN GEOMETRY AND ALGEBRA IN SECONDARY SCHOOL

Iolanda GUEVARA-CASANOVA
INS Badalona VII, ICE de la Universitat Politècnica de Catalunya,
Societat Catalana d'Història de la Ciència i de la Tècnica, Barcelona, SPAIN
iolanda.guevara@upc.edu

Abstract

The introduction of different procedures to solve problems in the mathematics classroom fosters the connection between contents and favours the students learning because it does not limit them to a closed and finished vision of the brought up problem.
The use of historical texts in the classroom is a good resource to show this variety of procedures, that enrich the learning and fosters a wider vision of mathematics as a science in continuous evolution.
The Nine Chapters on the Mathematical Art *(1st century AD), a classical reference text in ancient Chinese mathematics, contains more than two hundred problems that deal with subjects as diverse as calculation with fractions, use of proportions, root extractions, resolution of right-angled triangles, resolution of 1st and 2nd degree equations, and resolution of equations systems.*

Introduction

In this communication, we present a sequence of activities implemented to secondary school pupils, based on the problems of chapter 9 of *The Nine Chapters on the Mathematical Art*.

These activities have been designed from the fundamental figures described by Liu Hui (263) and Li Chunfeng (656) in the commentaries of the classical text, analysed in the bilingual translation by Karine Chemla i Guo Shuchun (2005) and following the suggestions by Siu Man-Keung (2000) on their pedagogical value.

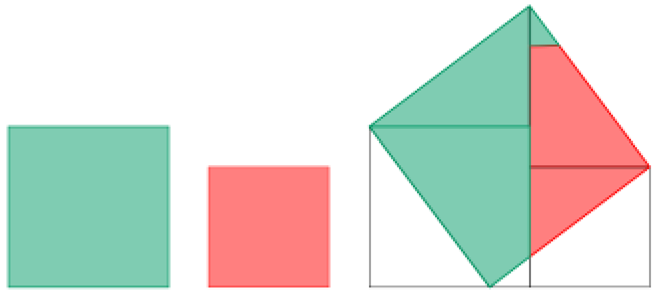

Fig. 1: Two squares and the bigger square which contains the other two.

The historical context

In 221 BC Qin Dynasty begins. Emperor Shi Huang Di, who became known as Shi Huangdi (First Emperor –literally: emperor begins) unified several walls made previously and began building the Great Wall of 5000 kilometres long.

They also built canals and bridges, which were intended to consolidate the power of the emperor, but also for public use.

Fig. 2: The Emperor, 221-210 BC.

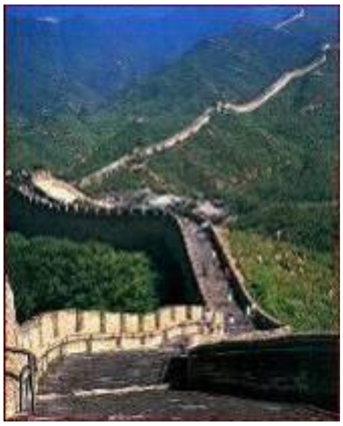

Fig. 3: The Great Wall.

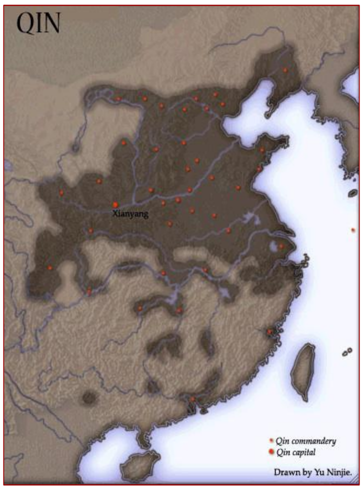

Fig. 4: China: Qin dynasty, 221-207 BC.

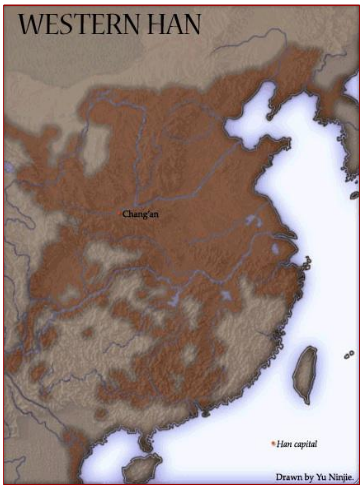

Fig. 5: China: western Han dynasty, 206 BC-220 AD.

Early Chinese texts in mathematics

The earliest Chinese texts devoted to mathematics that we know of date back from the time of the Han Dynasty (206 BC-220 AD). The unification of the Chinese Empire carried out by Qin Shi Huangdi (221 BC) and the subsequent consolidation of a centralized administration favoured the knowledge collection in different fields, and in particular those related to the field of mathematics

Suan shu shu, or *A Book on Numbers and Computations* (2nd century BC), discovered in 1984 in a tomb sealed in 186 BC, is considered the first known Chinese book strictly devoted to mathematics, related to administrative management (Qin / Han).

During the Han Dynasty, *Zhou bi suan jing*, or *Mathematical Classic of the Zhou Gnomon* (1st century BC) was written, a text related to topography, astronomy and calendar computing.

Fig. 6: Exemples of the bamboo strips on which the *Suan shu shu* is written. (Peng Hao, 2001).

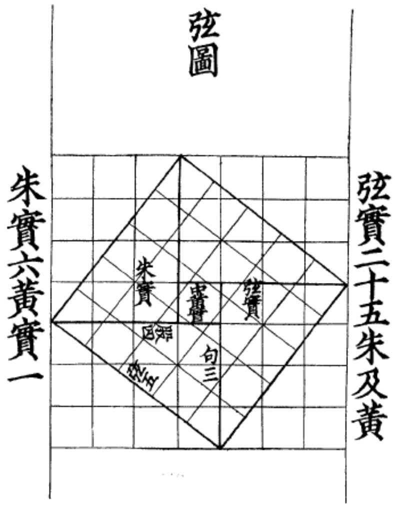

Fig. 7: Bao Huanzhi edition of *Zhou Gnomon* (1213).

The reference text

Our reference text is *Jiu zhang suan shu* (1st century AD), *The Nine Chapters on Mathematical Procedures* –from now on, it will be referred as *NC*.

It was a practical handbook for architects, engineers, surveyors and tradesmen. Candidates for civil service positions studied this text among others as a preparation for questions on the imperial examinations.

The 246 problems of the *NC* and their solutions show that the Chinese had access to a variety of formulas for determining areas and volumes of basic shapes, as well as methods for the solution of linear equations and equation systems with two and three unknowns.

They used a decimal numeration system, including decimal fractions, and were the first known society to use negative numbers in their calculations.

The classical text and the commentators

The first witness to designate the *NC* as a classical text is the commentator Liu Hui (263). Later, it will be the commentator Li Chunfeng (656) who will continue this tradition. Their aim was to prove the correctness of the algorithms used in solving problems by making each step explicit, explaining the meaning of each operation to get the final result, and to prove that this result corresponded to the question posed. They worked with specific problems and algorithms applied to specific data, but they described the procedure very carefully so that it could be used with other numbers.

BASE (*GOU*) ET HAUTEUR (*GU*)[1]

pour traiter le haut et le profond, le large et le lointain[2]

(9.1)

SUPPOSONS QUE LA BASE (*GOU*) SOIT DE 3 *CHI* ET LA HAUTEUR (*GU*) DE 4 *CHI*. ON DEMANDE COMBIEN FAIT L'HYPOTÉNUSE[3].

RÉPONSE : 5 *CHI*.

(9.2)

SUPPOSONS QUE L'HYPOTÉNUSE SOIT DE 5 *CHI* ET LA BASE (*GOU*) DE 3 *CHI*. ON DEMANDE COMBIEN FAIT LA HAUTEUR (*GU*).

RÉPONSE : 4 *CHI*.

(9.3)

SUPPOSONS QUE LA HAUTEUR (*GU*) SOIT DE 4 *CHI* ET L'HYPOTÉNUSE DE 5 *CHI*. ON DEMANDE COMBIEN FAIT LA BASE (*GOU*).

RÉPONSE : 3 *CHI*.

PROCÉDURE DE LA BASE (*GOU*) ET DE LA HAUTEUR (*GU*)[4] :

Le côté le plus court est appelé « base (*gou*) » ; le côté plus long est appelé « hauteur (*gu*) » ; ce qui lie les coins l'un à l'autre est appelé « hypoténuse »[5].

La base (*gou*) est plus courte que la hauteur (*gu*) qui lui correspond, la hauteur (*gu*) est plus courte que l'hypoténuse qui lui correspond. On s'apprête à les utiliser pour les appliquer à toutes les procédures (*lü*), c'est pourquoi on expose d'entrée de jeu cette procédure pour en faire apparaître l'origine[6].

BASE (*GOU*) ET HAUTEUR (*GU*) ÉTANT CHACUNE MULTIPLIÉE PAR ELLE-MÊME, ON SOMME (LES RÉSULTATS) ET ON DIVISE CECI PAR EXTRACTION DE LA RACINE CARRÉE, CE QUI DONNE L'HYPOTÉNUSE.

La base (*gou*) multipliée par elle-même fait un carré vermillon, la hauteur (*gu*) multipliée par elle-même un carré bleu-vert, et l'on fait en sorte que ce qui sort et ce qui entre se compensent l'un l'autre[7], que chacun se conforme à sa catégorie[8] ; alors, sur la base du fait que l'on garde ceux (les parties, les morceaux) qui restent sans les bouger, on engendre par réunion l'aire (*mi*) du carré de côté l'hypoténuse. « En divisant ceci par extraction de la racine carrée, cela donne l'hypoténuse. »

Fig. 10: Bilingual translation by Karine Chemla and Guo Shuchun (2005).

***The commentators and the* visual aids**

The first mentions in Chinese texts on ***visual aids*** are due to commentators. They consist in figures and objects introduced to justify calculation algorithms in the classical text.

As ancient texts carry with them the counting board, probably they also had some visual aids, i.e. flat figures to calculate areas and wood blocks for the volumes of geometrical bodies. From the 11th century on, texts include drawings.

Several authors like Christopher Cullen (1996), Karine Chemla (2005) and Joseph W. Dauben (2007) have called these figures ***visual aids***.

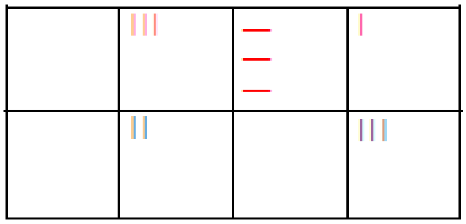

Fig. 11: The counting board.

***Description of* Nine Chapters**

The text in *NC*, as its name indicates, is structured in nine chapters.

- Chapter 1, *Fangtian* (Field measurement), discusses:
  1. how to calculate areas of cultivated land.
  2. how to do computations with fractions.
- Chapter 2, *Su mi* (Cereals), focuses on proportion problems, particularly those related to cereals exchange.
- Chapter 3, *Cui fen* (Distribution by proportion). It discusses problems related to proportional distribution, arithmetical and geometrical progressions.
- Chapter 4, *Shao guang* (What width?), deals with the calculation of side and length, when given an area or volume, as well as the procedures for determining square roots and cube roots.
- Chapter 5, *Shang gong* (Construction consultations). It discusses various kinds of calculations for constructions, in particular, calculations involving volumes of various solid shapes.
- Chapter 6, entitled *Jun shu* (Fair taxes), considers how to distribute grain and labour corves the best way based on population and distance between places.
- Chapter 7, *Ying bu zu* (Excess and deficiency), teaches a method of false position to solve certain types of systems involving two equations and two unknowns.
- Chapter 8 is entitled *Fang cheng* (Rectangular Arrays). It discusses solution methods for systems of simultaneous linear equations. Since negative numbers may arise through the use of this method, it also deals with the procedures for adding and subtracting positive and negative numbers.
- Chapter 9, *Gou gu*, deals with the Gougu theorem (Pythagorean theorem) and its use in solving right-angled triangles.

The text: base (*gou*) and height (*gu*) procedure

Chapter 9: Base* (gou) *and height* (gu)*: Solving the height and depth, width and length

24 problems on right triangles:

- Problems 1-12: procedure for base and height.
- Problems 13-24: ratio (*lü*), similarity between triangles.

The first problems in each block are geometric, with no context. Following them we find situations in context and the initial geometric situation appears.

The text: base* (gou) *and height* (gu) *procedure

In the classical text (1st century):

Base (*gou*) and height (*gu*), if each is multiplied by itself, joined (results) and divided by the square root extraction, the result is the hypotenuse.

Liu Hui (263) explains the vocabulary: The shorter side is called the base (*gou*), and the the longer side is the height (*gu*). The side opposite to the right angle is called the hypotenuse (*xian*). The *gou* is shorter than the *gu.* The *gou* is shorter than the hypotenuse.

Liu Hui (263) also explains the procedure: Let the square on the *gou* be red in color, the square on the *gu* be blue. Let the deficit and excess parts be mutually substituted into corresponding positions, the other parts remain unchanged. They are combined to form the square on the hypotenuse. Extract the square root to obtain the hypotenuse.

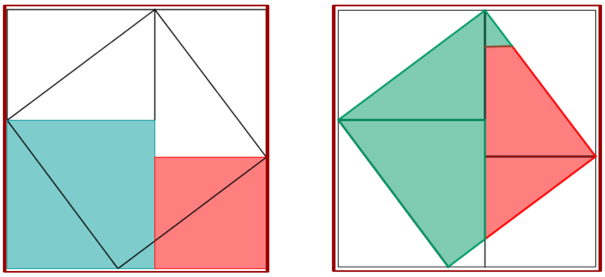

Fig. 12: Base and height procedure with diagrams.

The activities: Pythagoras' Theorem or *Gou gu* cutting and pasting

The area of the square on side ***c*** is the sum of the areas of the squares on the sides ***a*** i ***b***.

1. Construction of a square of side* c *from two squares of sides* a *and* b *respectively

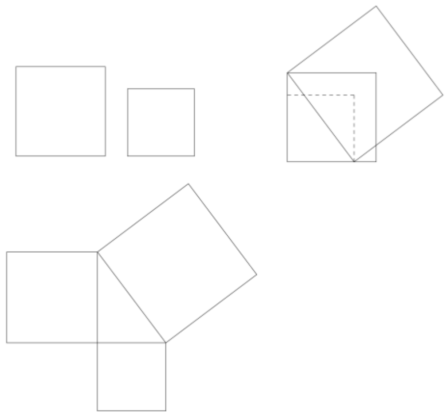

Fig. 13: Base and height procedure in modern notation.

Fig. 14: Construction paper.

2. The largest area of the square is the sum of the areas of two other squares

The proof –cutting and tracing figures or building the colour puzzle, cutting and pasting.

Fig.15: The puzzle of colours

3. Problem 9.5

術曰：以七周乘圍爲股[七]，木長爲句，爲之求弦。弦者，葛之長。

Suppose we have a tree 2 *zhang*[1] high and a perimeter of 3 *chi*. A climbing plant that grows from its base surrounds the tree seven times before reaching the top. The question is: how much is the length of the climbing plant? Answer: 2 *zhang* 9 *chi*, corresponding to shortlist (20, 21, 29)

Some help to solve the problem:

a) Roll up a sheet of paper forming a cylinder, simulating the trunk of the tree.

b) Draw the climbing plant around it.

c) Expand the sheet.

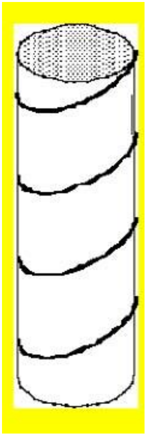

Fig. 16: The rolled paper and the climbing plant.

The activities: Construction of three key figures

1. The first key figure

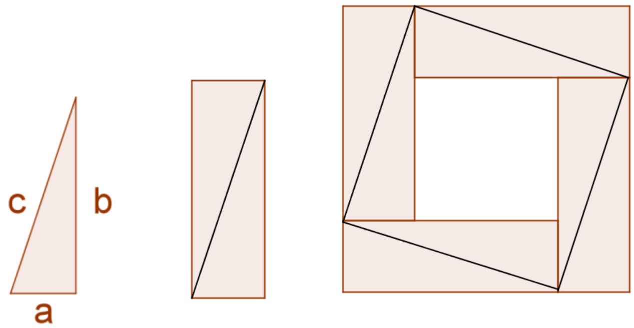

Fig. 17: Construction of the 1st figure.

It is the same initial square that we use to prove the *Gou gu* procedure. Fig. 19 shows the measurements of the square of side *a*+*b*.

[1] *zhang*, *chi*, *cun* are decimal unities, i.e. 1 *zhang* = 10 *chi*, etc.

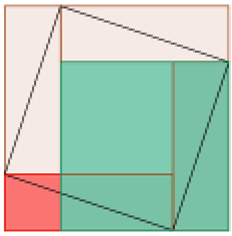

Fig.18: The 1st key figure with the initial two squares inside.

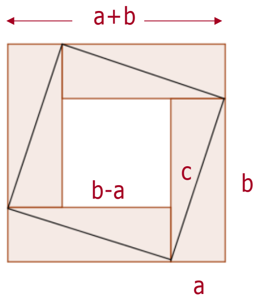

Fig.19: Relations inside the square.

2. The second key figure

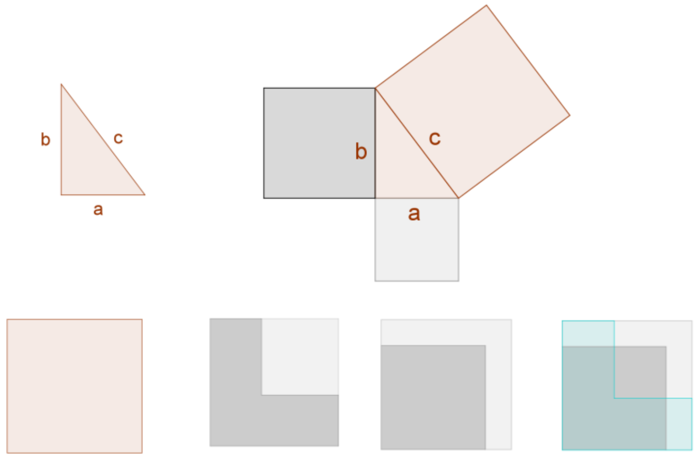

Fig. 20: Construction of the 2nd figure.

Measurements in the square of side *c*: the area of a square becomes the area of a gnomon and a rectangle of base *c*–*b* and height *c*+*b*.

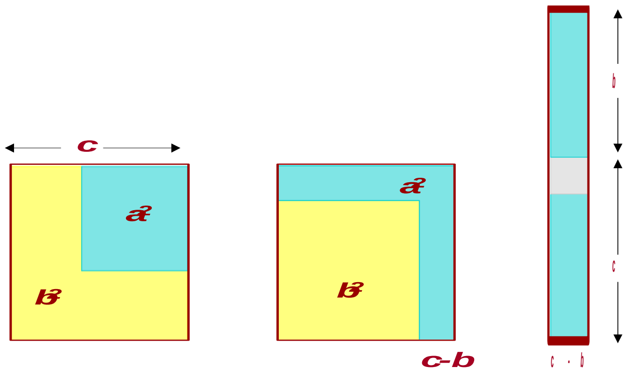

Fig. 21: The two gnomons and the rectangle of area b^2

3. The third key figure

Building a square of side $a+c$, and adding a rectangle of area b^2:

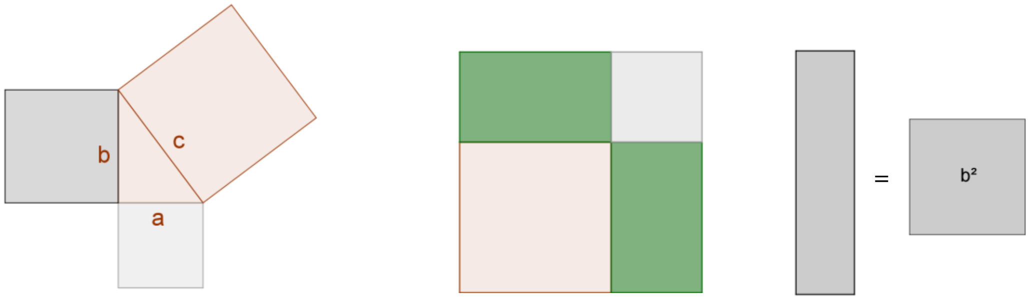

Fig. 22: Construction f the 3[rd] figure.

Measurements in the square, once added the rectangle of area b^2:

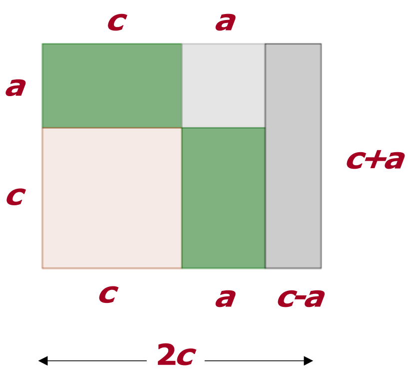

Fig. 23: Measurements.

name and picture	description	relationships
1st 	square of side a+b mark a in each side alternately.	c, b-a -> a+b -> a, b
2n 	square of side c within a square of side b, the gnomon has area a^2.	a, c-b -> c+b -> b, c
3rd 	square of side c + a add a rectangle of area b^2. 2c is the side of the new rectangle.	b, c+a -> c

Fig. 24: Summary of the three key figures.

The activities: Some problems solved with the diagrams

1. Problem 6

The classical text:

> Suppose we have a square pond of 1 *zhang* side in the center of which there is a rod protruding one *chi* from water level. When you pull the rod toward the bank, it comes just at the tip. How deep is the lake, and how long is the rod?

With visual aids, using the second figure: a=5, c–b=1, b=?, c=?

Answer: b=12, c=13

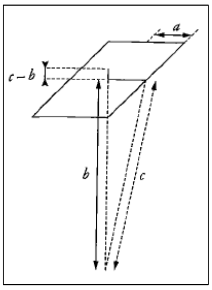

Fig. 25: Problem analysis, Karine Chemla, 2005: p. 667.

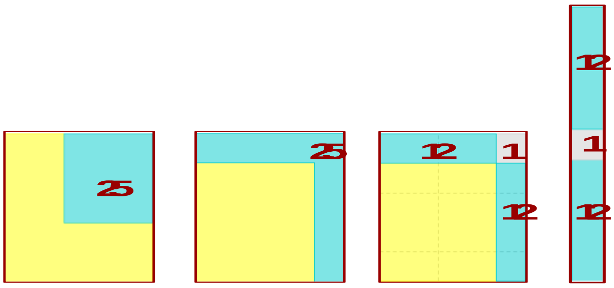

Fig. 26: Problem resolution through diagrams.

Some possible resolutions in analytical form:

- $a^2 + b^2 = c^2 \rightarrow a^2 = c^2 - b^2 = (c + b)(c - b) \rightarrow 5^2 = (c + b)\cdot 1 \rightarrow 25 = (c+b)$
- $c - b = 1 \rightarrow c = b + 1$; $a^2 + b^2 = c^2 \rightarrow 25 + b^2 = (b + 1)^2 = b^2 + 2b + 1 \rightarrow 25 - 1 = 2b$ $\rightarrow b = 12 \rightarrow c = 13$

2. Problem 11

The classical text:

Suppose we have a single leaf door where the height exceeds the width in 6 *chi* 8 *cun*, and where the distance between the two opposite angles is 1 *zhang*. How wide and how high is the door?

Answer: 2 *chi* 8 *cun* (width) and 9 *chi* 6 *cun* (height).

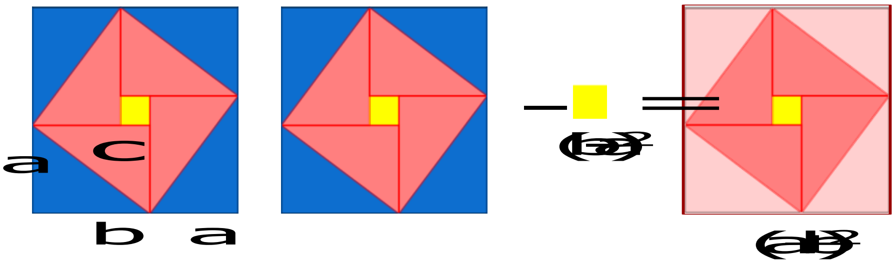

Fig. 27: Problem resolution through diagrams.

$b - a = 68$; $c = 100 \rightarrow c^2 = 10000 \rightarrow 2c^2 = 20000$

$(a + b)^2 = 2c^2 - (b - a)^2 = 20000 - 68^2 = 15376 \rightarrow a + b = \sqrt{15376} = 124$

$a = 28$; $b = 96$

Concluding remarks

The *Nine Chapters on Mathematical Procedures* is a classical text in Ancient Chinese Mathematics. This book, as several authors have pointed out (Man-Keung, 2000; Swetz, 1994), is still quite unknown in western mathematics education, but it contains a type of problems and solving approach that can result in a very prolific source of activities aimed at teaching maths.

The activities presented here are built from demonstrations and problems discussed in chapter nine of the text. It contains diagrams which are absent in the classic text but were incorporated by later commentators like Liu Hui and Li Chunfeng. These diagrams or key figures, as they are called by later historians, enable visual reasoning through geometry where this would appear to require more elaborate algebraic calculations.

It is a happy idea to use it in our classes when the algebraic language is still incipient in our pupils and students. Arguments used are based on the procedure of cutting and pasting and area conservation. The use of key figures (first, second and third) allow for a demonstration mode that combines numerical and geometrical reasoning. The application of this resource in teaching activities expands the students' possibilities of understanding because it opens two alternative, and at the same time complementary, ways of proof, both numerical and geometrical.

The examples presented were implemented in the classroom during the academic year 2009-10 at INS Badalona VII, in Badalona, Spain.

This communication is part of a broader research project entitled "The use of historical contexts in secondary mathematics classroom: The case of visualization of the geometry-algebra connection" in the form of a doctoral thesis in the Department of Didactics of Experimental Sciences and Mathematic of the University of Barcelona. In this work line during the academic year 2010-11, we have been discussing these and other activities undertaken by students during the academic year 2009-10. We have established a number of categories and studied the different processes that can be observed in problem resolution by students.

THE RECEPTION OF MATHEMATICAL KNOWLEDGE THROUGH EUROPEAN TEXTBOOKS BY THE GREEK INTELLECTUAL COMMUNITY IN THE 18TH CENTURY

Maria TERDIMOU
Hellenic Open University, GREECE
maria1979@her.forthnet.gr

Abstract

The subject of this paper is the transmission of European mathematical knowledge to Greece in the 18th and early 19th century, i.e. during the final decades before the Greek Revolution, mainly through mathematics textbooks. This event is illustrative of the dissemination of scientific information in the wider area of Europe.
In an age (the pre-revolutionary period), when there was an endeavour to advance Greek education and stimulate spiritual awakening, Greek scholars realised that the most important thing was not only or even mainly the production of original work, but the transmission of knowledge, in the form of translations or compilations, from Europe, where scientific and philosophical knowledge had long been developed to a high degree. And this was exactly what they did.
Of the 28 mathematics textbooks which circulated in printed form during the 18th and the first decades of the 19th century, 11 are translations of Western European works, such as those of Tacquet, Metzburg, Euler and others, while the rest are compilations, as is expressly stated in the title or preface of most. Apart from these, however, several other works which remained in manuscript form are also the result of compilation or translation efforts.

To begin, I would like to note that all the people mentioned in this paper are among the most important scholars of the Greek nation under Ottoman rule in the 18th and early 19th centuries.

The fall of the Byzantine Empire was followed by about two and a half centuries whose main feature was sterile scholasticism. Sciences became a marginal part of the curriculum[1], as Ottoman rule discouraged the diffusion of

[1] For more details, see M. Terdimou 2006.

contemporary theory and the Patriarchate remained staunchly faithful to theology and grammar as the only appropriate sources of education. During these centuries, Greek mathematical education was ensured by Byzantine reckoning manuals, Emmanuel Glyzonios's[2] *Arithmetic* (20 editions from 1568 [Venice] to 1823), and simple mathematical textbooks. Twelve anonymous Arithmetic manuscripts have been recorded up to and including the 17th century, with twelve anonymous manuscripts containing elements of Euclidean Geometry and two with excerpts from works by Euclid, Proclus, Psellos and Nicomachos Gerasinos (Karas 1992).

Of course, this situation arose from and was sustained by the particular circumstances of Hellenism, circumstances which not only did not stimulate interest in modern scientific thinking but even caused the isolation of the Greek nation from Europe. Thus, at the beginning of the 18th century, with rare exceptions (Sougdouris, Papavassileiou, Notaras), scholars had almost no scientific education.

In the late 17th century the Ottoman Empire, in its attempt to adjust to the new political climate developing in Europe, awarded privileges to the enslaved Greeks, who were eventually able to control trade and diplomacy to a great extent, especially following the Treaty of Küçük Kaynarca (1774), which contributed to the development of trade. The creation of the commercial class, the development of the Phanariot class and their rise to the rule of the Danube Hegemonies, resulted in the creation of novel views and a new intellectual awareness among the Greeks. More and more social classes realised that, from then on, society would improve only through knowledge arising from a systematic education and remediation of the sciences, and not through an empirical relationship with matters, which was no longer considered sufficient. The number of scholars studying in the West increased substantially.

During the first decades of the 18th century, the main places of study were the Italian universities, especially those of Padua and Pisa. During the last decades prior to the Greek Revolution of 1821, Greek scholars showed a preference for French and German or German-speaking universities (Vienna, Halle, Göttingen), particularly Vienna, where there was a significant Greek community and which was to become the most important publishing centre for Greek textbooks in the 18th century. It should be noted that during this period, there was a prevalent view that Germany boasted "first-class physicists and mathematicians", and that nowhere in the world were the natural sciences so solidly taught as at German universities (Karas 1993, pp 37-39).

After completing their studies, many scholars returned home, bringing with them the new scientific knowledge with which they had come in contact with. In other words, the return of sciences to the Greek intellectual world was a transference of knowledge from Europe, where the major scientific achievements of the 16th and 17th centuries had laid the foundations of modern mathematics and natural sciences. The channels of scientific thought traversing the Old World were gradually reaching the Greeks, in a typical example of the transmission of scientific knowledge in the wider European area.

From the first decades of the 18th century, efforts began for the foundation of schools and libraries, and the translation or writing and publication of mathematics textbooks to serve primarily educational needs.

Education was now organised, as it had not been earlier, and the rising commercial class was the most important social body for the cultivation of letters. Educators were no longer sought after in ecclesiastical circles alone, and the proposed education system began to specialise.

The number of mathematical works published, particularly from the latter half of the 18th century onwards, is impressive, especially compared to that of previous centuries. Approximately 30 titles were published, not counting commercial literature and equivalence tables. These are works of Arithmetic, Geometry and Algebra; some contain both Arithmetic and Algebra, while some even include Calculus.

On closer examination of these books, it is immediately apparent that 11 are translations of Western European texts, while the rest are compilations, as expressly stated in the title or preface of most of them[3]. Apart from these, however, several other works which remained in manuscript form are also the result of compilation or translation.

This observation, of course, is neither surprising nor impressive, but only to be expected: at a time when efforts were being made to improve education and awaken the intellect, scholars realised that what was most important was not only, or even mainly, the production of original works, but the transmission of knowledge, in the form of compilations or translations, from Europe, where scientific and philosophical knowledge were already developed. They knew that modern European thought, combined with their ancestral heritage, could reform the intellectual climate that had held sway over the enslaved Greek nation for centuries. They also knew that education is the strongest means of acquiring a national conscience, and therefore the best motivating force for people trying to gain their freedom. The following fragment from the Greek review *Kalliopi* (Vienna, 1819-1821) is characteristic of this mentality: *We steal ideas from philosophers and clothes from the erudite*

---

[2] Emmanuel Glyzonios or Glyzounis (1530-1596), from the island of Chios, studied medicine and letters in Italy. His *Arithmetic* was the master-key which covered the public's daily needs.

[3] Most contemporary works are "paraphrases, epitomes, compilations or simply translations of Western European works, from every branch of theoretical and scientific knowledge": Henderson (1977), p.17.

*to dress our nation. For this reason we came to Europe ... to steal from the original sources, from the best sources of what we do not have (*Karas 2003, p. 653).

The aim of translation is common to all: to benefit the Greek Race: "to benefit the Race I translated this book from the German into our own language, without taking the effort into account"(Kavras 1800, p. vii), says Zisis Kavras, while Psalidas states: "I wanted to translate the book "Mathematicae" of the Professor of Mathematics, seeing the use and benefit of mathematics to the public..." (Psalidas 1794, "To Anaginoskonti"), words used to justify their attempts to translate mathematical works. Koumas even promotes Psalidas's translation, writing, "But Psalidas by the *Mathematical Elements* of Metzburg, which he translated and taught, greatly benefited his countrymen"(Koumas 1832, p. 575).

In our opinion, this does not diminish the scholars' contribution and work in the slightest. The choice of subject for translation, if not made by chance, presupposes knowledge, consideration and a particular familiarity with the subject. The selection criteria, however, differ from person to person and period to period.

One of the first mathematical textbooks to be taught in contemporary schools, the *Introduction to Mathematics* (1695) by Papa-Vassilios, is a translation "from the tongue of the Latins". The same is true of the first printed mathematical book, published in 1749, the *Mathematical Way* by Anthracites, who had studied in Italy. Unfortunately neither of the original texts translated has yet been identified. Nor do we know the original of Glyzonios' s *Logariastike* (1568), the work reprinted most often for almost three centuries, although it is almost certainly some practical Italian Arithmetic.

The term Geometry at this time mainly referred to Euclidean geometry. A work of Geometry widely used by scholars was that of Andrea Tacquet (Netherlands, 1612-1660)[4], *Elementa geometriae planae et solidae, et selecta ex Archimede theoremata* (Antwerp 1654), a work essentially constructed from Euclid's *Elements* with material from Archimedes. It was translated into Greek, English and Italian (Gillispie vol. XIII, p. 235.). Many editions of *Elementa geometriae* were produced over the next 150 years: (1665, 1683, 1701 Antwep), (1761, Padova) and the revised editions by William Whiston (1703, Cambrige), (1725, Antwerp), (1727, London (English version)), (1745, Rome), (1762, Venice).

It was first translated into Greek by Eugenios Voulgaris (*Elements of Geometry*) in 1753-59 (Koumas 1832, p. 562), but did not circulate in printed form until 1805. Voulgaris used the Cambrige's latin edition revised by the protestant William Whiston, of 1703.

Voulgaris makes several interventions to Tacquet's text, both criticising Tacquet for omitting sentences from the *Elements*, and interposing many more proofs than the Euclidean ones in the original.

Approximately ten geometry manuscripts by Voulgaris have been recorded to date, all drawn from lessons he gave at the schools where he taught.

Iosipos Moisiodax also translated the same text, but his version remained in manuscript form (Moisiodax 1780, p. 43), under the title "Paraphrase and variation of Andrea Tacqet's Elementa…"[5].

N. Theotokis used Tacquet's textbook to write the first volume (Geometry-Arithmetic) of his three-volume *Elements of Mathematics* (1798). As for Benjamin of Lesbos, it is notable that Tacquet is the only European mathematician mentioned in the whole of his Geometry (Benjamin of Lesbos 1820, p. 59). From the study of the textbooks it also emerges that Benjamin was greatly influenced by Tacquet, probably via Voulgaris' translation.

The question that arises is why this particular text was so favourably received by Greek scholars. Iosipos Moisiodax justifies his decision to translate the textbook as follows: "I once translated the *Elements* of Andrea Tacquet and even his Trigonometry, both because that great man precisely follows Euclid, and because he is in this more accurate than any other of the moderns" (Moisiodax 1780, p. 43).

From another reliable source, European this time, we are informed that "this book of Tacquet' s was the most popular of all his works, and although it was no more than a paraphrase of works by Euclid and Archimedes, it was distinguished by the distinctness and clarity of the text. All his writings, in any case, played an important role in teaching, for whole generations of students were taught basic Mathematics from them" (Gillispie vol. XIII, pp. 235-236). This shows that the scholars mentioned did not choose this particular work by chance.

Another French mathematician whose mathematical textbook was translated into Greek, and moreover was the first Algebraic printed text, was Nicolas-Louis de Lacaille (1713-1762), professor of Mathematics at the Collège Mazarin, whose main work in Mathematics was *Leçons élémentaires de Mathématiques* (1741)[6].

---

[4] Andrea Tacquet (1612-1660) studied mathematics, logic, physics and theology at Louvain. He wrote many good elementary texts designed as mathematics textbooks for Jesuit colleges. *Elementa geometriae* (1654) was his most popular teaching work.

[5] Library of Roman Academy, Bucurest, MS 1513.

Thirty five years after the latin edition of 1762 (Vienna) Spyridon Asanis and Ionas Sparmiotes translated the first part of the work (pp. 1-133). It was published in Venice in 1797, under the title *Elements of Arithmetic and Algebra.* The translators possibly used this latin edition of the work.

Regarding the above translation, Koumas notes that "Asanis enhanced it with much useful information on analysis and thus the first Algebraic text appeared through the medium of the press to the Race" (Koumas.1832, p. 575). In other words, this book is the first text purely concerned with algebra to circulate in Greek. From 1797 onwards, the appearance of this first complete algebraic textbook in Modern Greek education contributed, among other things, to the gradual creation of a dynamic in the area of algebraic education, something reflected in the burst of publishing in the field of Algebra from this point on.

The second part of Lacaille's work translated by Asanis and comprising Geometry, remained in manuscript form[7]. The third part was translated by Asanis and Koumas, and printed in Venice in 1803 under the title *Analytical Treatise of Conic Sections*. The translators also used the latin edition (1762) of the work.

Moisiodax translated this textbook as well (Moisiodax 1780 p. 44-45) but his translation has not survived. He describes the book as follows: "The most illustrious de Lacaille in two minuscule volumes discusses everything to do with either analytical or synthetic Mathematics, beginning as an introduction with Arithmetic...." (Moisiodax 1780, p. 44-45). Thus, Moisiodax regards it as a work suitable for teaching, something confirmed by the large number of reprints in the West. Moisiodax used Lacaille's text in teaching Mathematics at the School of Iasio.

Another favourable opinion of the book is contained in an 1818 issue of *Logios Hermes*, where it is described as follows: "This book, albeit in a single volume, contains the most essential and basic elements of almost all pure mathematics..."[8].

The work of Leonard Euler (1707-1783) could certainly not be absent from the translational interests of Greek scholars. An extract from the work *Eléments d'Algèbre, par M. Leonard Euler traduits de l'allemand…* (Lyon, 1774), a French translation of the *Vollstandige Anleitung zur Algebra* (St Petersburg 1770), was translated by Ionas Spermiotes[9].

According to information from *Logios Hermes*[10], the original of the textbook translated from the German by Zisis Kavras, the *Elements of Arithmetic and Algebra* (Jena 1800) was also by Euler. We believe that this really is a translation of the above work, which, according to Dirk Struik, "was the template for many later Algebra texts" (Struik p. 198) We do not know why Kavras' name is not mentioned either in the preface or on the title page; there is just the note "Translated from the German by a fellow countryman who loves his race, for his fellow countrymen". The absence of Euler's name is no surprise, as contemporary authors did not feel it necessary to acknowledge their sources in any form. Stefanos Dougas also recommends this text by Kavras as the most suitable for beginners.

"Asanis decided to write a textbook on differential and integral calculus, and he translated this great and erudite text by Euler" (Gedeon 1976, p. 181). This mention by Manuel Gedeon is the only information we have on the translation in question, which, if it was ever written, has not yet been found.

Athanasios Psalidas and Michael Christaris chose to translate a textbook by G. I. Metzburg. "I wanted to translate the book 'Mathematicae' by the Professor of Mathematics, who taught here at the Academy [of Vienna] for more than twenty years, because this treatise is intelligible, methodical and succinct..." (Psalidas 1794, pp. xiv, xv.), stressed Psalidas in the preface to his *Arithmetic*, the first volume of his work (Vienna 1794). It contains many alterations to the original text, as he says himself. The original, entitled *Gl. Georg Ignat L.B. de Metzburg, Mathematicae in unsum Tironum Conscriptae. Tom. I. ed. IV*, Vienna 1793, was the Latin translation from the German. This transmission of mathematical knowledge was rooted in the learning environment offered in Vienna, where Psalidas had studied from 1787 to 1795.

The second volume was to remain in manuscript form (Karas 1992 p.153). A full translation of the work was presented by Michael Christaris, entitled *Elements of Arithmetic and Algebra* (Padua 1804). The translator preferred the German edition of Metzburg's textbook, *Des Freyhernn von Metzburg... Arithmetik und Algebra* (Vienna 1788). Christaris does not give a specific reason for choosing this particular work. His choice was probably not based on his own informed opinion of the book, as he was a doctor rather than a mathematician. We should not overlook the fact that Metzburg was roughly contemporary with Psalidas and Christaris, and that Greek scholars generally tended to translate new texts

---

6 Nicolas-Louis de Lacaille (1713-1762) mathematician and astronomer. His mathematical work *Leçons élémentaires de Mathématiques* (1741) was frequently reprinted (1764, 1768, 1770 and 1778), revised by Abbé Joseph-François Marie and translated into Latin, Spanish, Italian and English. Nielsen (1935), p. 221.

7 Library of Milies, MS 6.

8 *Logios Hermes*, 15 August 1818, pp. 420-424.

9 Olympiotissa Library, MS 43.

10 *Logios Hermes*, 20 October 1811, p. 355.

appearing in Europe for the first time. The ultimate aim, as we have said, was the transference of modern knowledge. This aside, however, Metzburg taught at the Academy of Vienna for 24 years (Psalidas 1794, p. iv), meaning that his work had already been tried and tested as a teaching textbook.

Christian Wolff (1679-1754) is better known as a philosopher than a mathematician. The Latin translation of his mathematical work (Halle 1717) (Gillispie vol XIV, p. 483) *Elementa matheseos universae* (Halle 1730), comprising two volumes, *Elementa arithmeticae and Elementa geometricae*, was quite widely used by Greek scholars.

Nikolaos Zerzoulis translated the whole of Wolff's textbook, as his surviving manuscripts attest. Wolff's work also certainly aided Theotokis in writing his *Arithmetic*.

Dimitrios Govdelas makes several references to Wolff in his book on algebra (Govdelas 1806, pp. 8, 422, 441, 510), and drew on the German scientist's work for his own textbooks (Camariano-Cioran 1974, p. 232).

The work *Cursus mathematicus* (Halle 1758-1767), by Segner (1704-1777)[11] was also chosen by Voulgaris as a suitable subject for translation, which was printed in 1767. Voulgaris justifies his choice in the preface, saying that "The German Academies, which are among the most celebrated in Europe, approved the Man's works as absolutely accurate".

The *Geometry* of Octavian Camett was translated by Dimitrios Razis because, as he says, "Camett set the Euclidean elements in a new order and applied a more comprehensible method" (Razis 1787, p. 12) and was published in Venice (1787).

Spyridon Asanis and Ionas Sparmiotes chose to translate Grandi' s (1671-1742)[12] *Conic Sections* (Florence 1750) in order to reinstate ancient mathematical learning, as always in the service of the Greek Race. The original text is the *Sectionum Conicarum Synopsis clar. viri D.Guidonis Grandi et Schenatibus aucta Ad. Octaviano Cametti*.

The work *Les éléments d' Euclide de M. Ozanam... démontrés d'une manière nouvelle et facile par M. Audriene* by Jacques Ozanam (1640-1717) was used, among others, by Nikiforos Theotokis in his *Geometry*. Ozanam was only a minor mathematician, but he wrote books many of which became very popular and were often reprinted (Gillispie vol. X, pp. 263-265).

In his chapter on "Conic Sections", Theotokis drew on Josepho Orlando's *Sectionum conicorum tractatus* (Naples 1744) (Karas 1992 p. 94).

In a manuscript by the same scholar entitled "Elements of Arithmetic and Geographic Science...", one section consists of "The Interpretation of the Logarithmic book by Gafendi, translated from the German into the Greek tongue" (Karas 1992, p. 96), which, however, is not included in the printed edition.

Alexis Clairaut was one of the French mathematicians linked to the philosophers of the Enlightenment. An extract from his work *Eléments de la Géométrie. De la mesure des figures et des solides* was used by Ioannis Phournaios in his Geometry, as he notes in one of his manuscripts: "Additions to Clairaut's Geometry. On the transformation of shapes"[13].

When writing a Trigonometry textbook, Phournaios also used the *Cursus Mathematicus…* by Gaspar Schott, as he mentions in a manuscript[14].

Koumas informs us that his eight-volume work, including Mathematics and Physics, is a translation from the French of a work by Jean-Claude Fontaine (1715-1807), professor of Physical and Mathematical Sciences at Turin University. This compendium had been recommended to him by Remigius Döttler (1748-1812), professor of Mathematics at the University of Vienna (Koumas 1832 p. 588). The work is Fontaine's textbook *Cours Encyclopédique et élémentaire de Mathématique et de Fysique* (Vienna 1800). During the course of translation, Koumas was unsatisfied with the result and carried out alterations to the material, using other, mainly French texts by modern authors Abbé Saury, E. Bezout and S.F. Lacroix (Koumas 1807 p. χβ.).

Koumas's *Synopsis of the Sciences for Beginners* is also a translation from German, as he says in the preface: "Second I placed the Geometry, having translated this also more freely than the Arithmetic, from the book written in German.entitled *Introduction to Geometry* (*Anleitung zur Messkunst*) used in the schools of the Austrian Empire" (Koumas 1819). Clearly, the original was a simple teaching textbook or books, but the author is not mentioned.

In a textbook on Spherical Geometry, Christoforos Koutaleus states that, "I copied sentences 46, 73, 75, 77, 89, 103, 114 from Korganov's geometry"[15]. Korganov was professor of Mathematics at a Russian school in St Petersburg.

---

[11] Segner was Professor of Mathematics and Physics at Göttingen University (1735-1755). and later at Halle University. Cf. Gillispie, ibid, vol. XII, p. 283.

[13] Romanian Academy Library, Bucharest, MS 740.

[14] Ibid, MS 1369.

Konstantinos Doukas, in the "Prelude" to his textbook *Practical Arithmetic* (Vienna 1820), expressly states that his work is a compendium of the three-volume work on arithmetic by S. Guntz, professor of Mathematics and headmaster of a school in Prague, with his own additions (Doukas 1820, "Proimnion", p. 1).

We also have some information on translations of works which remained unpublished or have been lost along with the corresponding manuscripts. These include translations of works by Jean-Batiste Biot, A. M. Legendre, S. F. Lacroix, Blaud, Hotzapfeln and others.

It should be noted here that, if we list the European authors whose works were either translated (whether published or unpublished) or used in compilations by Greek scholars, particularly during the last decades before the Greek Revolution and the two immediately following (Legendre, Lacroix, Mauduit, Biot, Bezout, Abbé Saury, Francoeur, Fontaine, Clairaut, De Lacaille, Camett, Ozanam, Euler, Metzburg, Segner, Wolff, Grandi, etc.), we see that most of them are French and German scientists. This, of course, is due to the fact that Greeks at the time studied mostly at French and German-speaking universities, where they would have come into direct contact with the works of the scientists mentioned above. It should also be added that most of the publications were printed in Vienna.

To sum up so far, we may say that all Greek mathematical textbooks were either translations or compilations of Western European texts, with the ultimate aim of transferring both Ancient Greek mathematical knowledge and modern scientific thinking. The scholars' basic criterion in selecting the originals was whether they constituted a modern proposal, whether they corresponded as far as possible to the scholars' own views on science, and whether they could be used as teaching tools.

HISTORY OF SCIENCES AND THE TEACHING OF LIFE AND EARTH SCIENCES IN FRENCH SECONDARY SCHOOL. WHAT KIND OF TEACHER'S TRAINING AND WHAT KIND OF TEACHING?

Pierre SAVATON
IUFM – Institut Universitaire de Formation des Maîtres, Université of Caen Basse Normandie,
Centre François Viète, Université de Nantes, FRANCE
pierre.savaton@caen.iufm.fr

Abstract

*Since 2005, learning programmes of Biology and Geology of pre-academics classes (pupils from 11 to 18 years) indicate that it' possible to introduce some elements of history of sciences relating to the science's concepts studing into these classes. Bu, It's just a possibility. Sciences teachers must follow the experimental method and not the historical one. It's through an investigative approach (*démarche d'investigation*) that historical elements can be used as well as experimentation or studies of current scientific documents. Usually the university training of Biology and Geology teachers does not include studies of history of sciences and the in-service training of teachers (of the national education) does not include training courses in history of sciences neither. Thus, teachers must be trained by themselves if they want to introduce elements of history of sciences into their sciences courses. The new textbooks present some pages of historical data, reduced to some lines of an historical source and some lines of context, or even just a photograph of a great scholar. There is a risk to reduce history of sciences to an illustrative and anecdotic role.*
This assessment established, the communication will discuss the reasons which are opposed to a real introduction of history of sciences into secundary courses of sciences, and which explain the lack of sciences history courses in teachers training.

What about sciences teachers training and competitive examination?

1. Recruitment of French state secondary teachers

First of all, we must have in mind the organization of our French secondary educational system. Teachers of the state secondary education are state civil servants, recruited by two distinct national competitive examinations: the "*Certificat d'aptitude au professorat de l'enseignement secondaire*" or the "*Agrégation*". From the 2011 examination, candidates must be master degree holders to be appointed in a secondary school. Until 2010, candidates had only to be holders of a licence degree, and most of them prepared examination in one year of special training within IUFM (*Institut universitaire de formation des maîtres*). At that time laureates were appointed both in IUFM to follow a professional training, and in a school as a teacher, teaching and being trained at the same time. Since September 2010, laureates (and also master holders) are directly posted in a school.

This recruitment mode on national competitive examination of the tenured teachers assures a big homogeneity in the teacher's initial training. Secondary education curricula being also national, the whole secondary education system presents a very strong structural and functional homogeneity. It is necessary to keep all these characteristics in mind, to measure the place of the history of sciences in French teaching of biological and geological sciences.

2. Teaching of life's and Earth's sciences in French secondary education

French secondary education includes the teaching of life sciences and Earth sciences ("*sciences de la vie et de la Terre*" or its acronym "SVT") from the first year (11 years old) up to baccalaureate (18 years old). This teaching is compulsory from first up to fifth year, and then compulsory, optional or absent in sixth and seventh years depending on the section. SVT is taught in the secondary since the setting up of the secondary education system in 1795. Many reforms, which went down in history of our education for two centuries, established step by step SVT as a general education subject, at least for most of the pupils.

For more than 150 years, the official syllabus of SVT has regularly recalled the possibility of introducing elements of history of sciences (HS) in the SVT class, but this possibility was never translated to a true introduction (Savaton, 2011). In 2001, the fifth year's syllabus of SVT proposed the introduction of some historical presentations of some scientific concepts studied in class, justified for cultural reasons.

"Science is not made of certainties, it is made of question settings and answers, which evolve and change with time. In many instances, nothing can replace historical account. This one has an irreplaceable cultural side, which locates scientific discovery in its temporal context but also shows how scientific discoveries influenced evolution of history. Historical account allows for measuring the difficulty that humanity met to resolve problems which can seem elementary today".

The 2005 secondary school new curricula (from first up to fourth year) have wished to develop inquiry-based science teaching (IBST), and proposed to introduce elements of history of sciences as a support for studies and exercises. Pupils must be able to locate scientific discoveries in time, and to conduct a critical study of historical texts. Examples are proposed: elements of history of digestion, blood circulation, antibiotics discovery or the Evolution theory, study of texts by Wegener on the continental drift, etc. It is not proposed to teach HS, but to use HS elements to teach SVT. The fifth year's class new syllabus on 2010 reduces the volume of knowledge to be acquired "to allow teachers to devote time to make understand what scientific knowledge, its mode of building, and its historic evolution, are". Processes based on history of sciences become an optimum way to develop IBST.

"History of scientific knowledge development, of its modification in the course of time, is useful means to include the nature of scientific knowledge and its mode of building with its advances and possible declines. It will be necessary to make sure that this approach does not lead to the simple evocation of a factual succession, and not to caricature this history so as to give a false idea of scientific demonstration; if some arguments have a major historical importance, it is rare that only one of them is enough to draw away a decisive evolution of scientific knowledge".

In 2011, in the scientific section of the sixth year, teachers will have to introduce some aspects of the history of the plate tectonics model. The main scientific lines of this model are studied in the third year, then completed in this sixth year after this historical study. It is the first time that an SVT curriculum invites teachers so apparently to introduce elements of history of sciences in concept or model teaching. In fact, the purpose is not to teach HS, but to introduce an historical epistemology (no an epistemological history). This teaching will introduce epistemology elements in the teaching of sciences; but to avoid a teaching of general epistemology, too much impregnated with philosophy of sciences, the syllabus *concepteurs* wanted to anchor them in the history of sciences. There is a will to introduce local (or regional) epistemology.

3. History of sciences in the university curricula of life's and Earth's sciences

It's rare to teach HS in university curricula of life's and Earth's sciences. Few universities offer courses in history of sciences, but when it is so, they are often of few hours. In the 1980s and 1990s, an optional course of history of sciences often took place in first and second years of sciences curricula, especially in mathematical or physical sciences sections (fewer in biology and geology). The university curricula reform in the 2000s and the creation of new licence and master degrees (LMD) often ended up with the disappearance of this teaching. The history of sciences, except in some special curricula, is present only in medicine and in engineers' schools, with very different contents and objectives.

European reform of LMD gives the students the possibility of building their own certificates by choosing their courses. But the reality of French university functioning is very different. Every university built its certificates by establishing a number of compulsory courses and offering some optional courses in the scientific domain of the certificate. It is therefore difficult for a student to really build his own certificate. It is a scientific choice also forced by organizational aspects like timetables or requirements on the minimum number of students to open a course. But such choice reduces introduction of HS very strongly.

4. Teachers training in university institutes of teachers training

Until 2010, the IUFM organized the preparation of the competitive examination and the professional training of laureates simultaneously. The year devoted to the examination preparation (PLC1) was almost exclusively dedicated to study subjects for the examination tests. Without tests about history of sciences, it was exceptional that IUFM offered a course of sciences history in PLC1 (Savaton, 2006). On the other hand, several IUFM included some hours of training in sciences history in the curriculum of the first training year of the civil servant trainee (PLC2). With few hours, it could only be some chronological landmarks in the HS, a study of an historical controversy, or a critical reading of texts. Ambitions were limited to introducing an historical perspective to think about the making of science, the discourse of sciences (with a very epistemological view), or limited to bring historical elements in support of a didactical discourse about the construction of the pupil's knowledge in school situation, or about special didactical or pedagogical tools to build their course.

A symposium organized in Montpellier (France) in 2005 by a group of investigators in history of sciences appointed in several IUFM (REFOREHST group: *http://plates-formes.iufm.fr/ehst/rubrique.php3?id_rubrique=6*) allowed to discuss the results of an inquiry about the EHST in courses and teachers trainings in IUFM. Most of the time, these trainings were very limited and depended on local leadership of few people.

The new masters creation specifically intended for the future secondary teachers, on September 2010, and the universities new autonomy let some people think that it could be changed. Each university set up its own certificate by associating courses on life's and Earth's sciences, didactical courses, practice in school, foreign language courses, and training in the use of information and communication technologies in education (ICTE). Half of them have introduced a course of history of sciences in masters in their first or second year. Courses of up to 50 hours are offered either alone or linked with epistemology and didactical courses. The 2002 national official texts, which specify the competences of future secondary teachers, pointed out that they should not only be specialists on scientific knowledge of their discipline, but also on history, epistemology and didactic of their discipline. But, as we will specify further, the absence of real recognition of these abilities in competitive entrance examinations tests reduced the weight of this text. The diversity of situations from one university to another, explained fundamentally by the building conditions of these new certificates (a certificate is often built and carried out by a group or some laboratories: it is not indeed a collective work including opinions and competences of all the actors in the university) and, locally, by the existence or not of research laboratories, teachers or investigators in history of sciences. In the absence of a true national framework, and in the emergency (new certificates should have been built in only some months), local powers were often decisive.

5. State competitive teacher's examinations

The reform of university training of future secondary teachers is the direct consequence of the reform of recruitment conditions of these teachers and of the competitive examination. Tests have been changed, both in their contents and in its form. But if tests are determined by official texts, their organization depends on the jury. Every school discipline has its own jury, composed of academics, teachers and pedagogical inspectors of secondary. The nature of the questions and their weight are determined by the jury composition. No historians of sciences were to be part of the 2011 jury for competitive examination of SVT teachers, even if official texts speak of recruiting secondary teachers who know the history of their disciplines. The jury, and with them general inspection of the secondary and scientific academics, do not like questioning candidates beyond very general knowledge in history of sciences, in the line of the general knowledge which is not specifically taught.

Recruitment by a competitive examination is a system which reinforces the university study of disciplines that the candidates will be questioned about in competition, and reduces or abolishes the university study of disciplines about which the candidates will not be, or not much, questioned. All investigations about examination history and curricula history have showed this very fact.

Obstacles or oppositions to the teaching of HST?

With or without these new SVT curricula in secondary education, history of sciences is little taught. During the Congress of the French Society of HST (SFHST) in 2004, a symposium called: «Teach the history of sciences today» (organized by Danielle Fauque and Hélène Gispert) has given us the occasion to discuss about obstacles of the history of sciences teaching in the teachers training. I raised then 4 arguments regularly opposed to this introduction: lack of time, absence of need, opposition between letters and sciences, relegation within the general knowledge (Savaton, 2004).

My analysis of obstacles and oppositions is based on my experience as a teacher, as a training officer in IUFM and as a lecturer in Earth's sciences and in history of sciences at the university. It is also based on my recent experience in the constitution of new masters, intended for secondary teachers, and at least on my research about the curricula history of life's sciences and of Earth's sciences in the secondary for two centuries.

Two types of blockages are found, in secondary education as well as in university, in the syllabus as well as in individual discourses: structural oppositions (construction conditions of certificates syllabus, discipline sharing out, length of school and academic years, competences of the teacher) and epistemological oppositions (interest of the history of sciences in sciences teaching). But this simplified categorization should not conceal the complexity of resistance, inertia and obstacles which very often blend several factors. I would try to present this question in the case of secondary education.

1. The «feeling of incompetence»

Teachers often declare themselves unable to introduce elements of history of sciences in their sciences lessons. Absence of an initial university training and lack of permanent professional training (hard reduction for several years) force teachers to form by themselves through readings. The schoolbook often becomes the only working source for teachers practice. Their treatment of HS is often limited to some pictures, some little text extracts or some dates in a discoveries chronology. Such sources don't push teachers to introduce elements of history of sciences; they only allow for adding a name or a date to the list of knowledge to be learned or to serve as motivation elements or attention trigger by their originality with regard to the class habits of the courses. When they present history of sciences, curricula official texts are instigations, not obligations. Pedagogical inspectors (ancient teachers) are not better formed in history of sciences and do not flourish either in this direction (their little support to the introduction of the HS in permanent training is eloquent).

This unpleasant feeling of incompetence can lead either to ignore instigations, or to protest against its introduction, according to people and contexts (establishment contexts, academy contexts, official texts comments). This opposition often relies on the argument of lack of time (not enough time to teach the whole syllabus) or of the pedagogical choice. This pedagogical choice can question the interest of HST by reporting absence of need (HST would be only a means among others), not enough pertinence (there are more efficient means) or "counterproductive" effects (the study of HS with its doubts, its dead ends and its historical "errors" would unsettle ongoing trainings).

2. The lack of time

The secondary syllabus is regularly reported as being overloaded, and the teachers first objective is often to finish the syllabus. Any pedagogical innovation requires more time and therefore leads to a slower progress.

Lack of time isn't an easy argument or a false argument in an educational system which cuts every discipline in a list of knowledge to acquire per year, and turns this knowledge acquisition into a condition of schooling success. Each pedagogical choice must take care of time. Study of historical texts needs time. The use of the historical method needs more time than the classical method, something between the dogmatic method and the inquiry method. Syllabus proposes the use of elements of HS in the inquiry method. This problem of lack of time has been regularly put forward, in the history of SVT teaching, against the introduction of an historical method. It is a time investment which requires that teachers are persuaded of the huge interest which there would be for their pupils to adopt it. It is one of the reasons why syllabus proposes to use historical elements in an inquiry method, and does not propose to use the historical one.

What can we do in two or four hours to study the history of Plate Tectonics Theory with sixth year pupils? No history –We don't have time to study texts and to understand their contexts. We'll just have time to present main ideas of one of the controversies which marked this history, and maybe to expose the conditions of its solution. School training time of is not the same as university teaching time, so we must test what kind of HS we can do in the time we have, and not project the time we need for what we want to do. Otherwise, we risk never having the necessary time to test an introduction of HS.

3. The epistemological obstacle

French secondary education in the 19th century is dominated by the teaching of letters. The introduction of sciences curricula was made at the price of a conflict with classical letters. The importance of sciences and technologies in the development of industrial societies at the end of the nineteenth century and in the beginning of the twentieth century reversed hierarchies and sciences became the determining syllabus for pupils' selection and career choice. In a system of hierarchy between school disciplines, life sciences and Earth sciences (the third in the order of sciences after mathematics and physical and chemical sciences) did not cease stressing their nearness with mathematical, physical and chemical sciences. This discipline changed its name in 1902, from *natural history* to *natural sciences*. It is not anecdotic.

Opposition between sciences and letters is very marked in the teachers discourse (and by impregnation in the pupils discourse), who distinguish those with a literary bent and those with a scientific bent. The first would be characterized by taste for detail, fancy and creativity, and the second, by taste for the essential fact and method. The history of sciences is received as an external view of letters about sciences.

Official instructions haven't ceased to remind teachers that they have to develop the scientific mind of their pupils but haven't added, until today, that HS could help to do it. Today, new SVT syllabus introduces history of sciences as a mean of scientific mind training for the critical detachment which it can bring. But, teaching practice depends of tradition, and changing the mind of official instructions is not enough to immediately change practice and representations by teachers. Wishing today that sciences teaching include elements of history of sciences to correct misrepresentations, is conceding that sciences teaching in these last years neglected its contribution. It is citicizing the sciences teachers community, declaring today that an historical lighting is otherwise essential, at least useful to build a better representation of science. Many teachers don't understand the reasons why they would have to teach "errors" and "dead ends" of the past while they miss time to teach the results of an up-to-date science. They justify the social importance of their discipline by the role of sciences and technologies in the development of our societies. They don't wonder about the nature of scientific knowledge which they try to transmit to pupils, because of a kind of naïve positivism which push them to keep mixing up science and progress, science and truth, and to refuse linking science with human mind, with societies, with powers, with ideologies, etc. This obstacle is not the least that we have to overcome to change the practice.

Conclusion

To conclude in a perspective of teachers training, the introduction of some little elements of history of sciences in the new SVT syllabus of secondary education could be an opportunity for secondary teachers to think about the nature of the science they teach and about the way they teach it. But for that, it could be necessary that our whole teachers training system, from the university syllabus up to the national competitive examination tests and permanent training, question their own representation of the nature of scientific knowledge and try to introduce an historical dimension.

As long as the university syllabus of sciences don't introduce HST into the students training, I'm afraid that this attempt of the secondary education syllabus to introduce elements of HS will be just one more invitation in the long list of never applied instructions. But introducing HS in science teaching needs to be discussed and specified. HST for what? For itself? For epistemological teaching? Who will teach HST in universities? Who will teach HST in initial and permanent teachers training? There are a lot of questions which should be answered before.

WHY CAN IT BE DIFFICULT, ESPECIALLY FOR BIOLOGY TEACHERS, TO USE ON-LINE RESOURCES IN HISTORY OF SCIENCE FOR INQUIRY-BASED SCIENCE TEACHING?

Abstract

We think that history of biology helps the understanding of scientific inquiry by pupils, and we prepare to offer some on-line resources for them. But then, how can we help teachers to use this means? And why do they need help specially in biology? In 1994, Charles Darwin's Theory of Evolution appears for the first time in France in the biology syllabus. A few years later, it is already forgotten. Teachers prefer teaching facts and evolution mechanisms rather than the evolution theory because students had many questions about moral and religious values. So why this confusion in science classes? Perhaps because students do not understand the scientific process. They do not know the nature and construction of a scientific theory. They do not understand that sciences only give us knowledge and means to understand the world. However, in the study of biology, moral values mobilized by the studied objects are often very important. The study of life –its fragility, history, links with the environment– affects us directly. But these values change with time. For example, talking about the link between other animals and humans is less difficult today, but it still affects some students. The use of resources in history of science can remove these difficulties. But, if we want history of science to help teachers to teach scientific methods and pupils to understand it, it is necessary to know the scientific concepts, the investigation method , but also the historical transformations and implications of these moral values. So when in France, and may be in Europe, we want to offer on-line resources in history of biology, we have to discuss about this sort of problem. What on-line resources in history of biology should we give to the teachers?

"If we had a real education system, there would of course self-defense intellectual."
Noam Chomsky.

In 1970, French Nobel Prize of Medicine Jacques Monod (1910-1976) declared that "true knowledge doesn't know of moral values": he excluded individual or collective ethics from his investigations for being "inherently non-objective", whatever the form: moral, religious or political discourses. Moreover, Sciences are intended to "attempt to values" –meaning "contemporary legacies secularised religious or philosophical myths of past centuries."[1] We often hear that "Sciences are amoral", but are scientific data devoid of any moral implications when we teach them?

Yet, these "moral implications" are most problematic for sciences teachers, and maybe for biology teachers. When they try to teach an investigative approach to science, using texts or images from books or on-line resources, they often find big problems with their students. But it's still worse when it is the theses from these on-line resources which raise a problem, because they have no historical and philosophical vision of the compound scientific question. Teaching sciences through on-line resources but without knowing history of sciences and epistemology is really a big, rather urgent and dramatic problem.

A first example on a French web for teachers

We want to begin with a recent example. It is not an historical example, but it concerns our subject because it has to do with the human being and the environment, and this text has a historical dimension. This is an on-line resource for French teachers in primary school. It's name is *My home, my planet... and I!*[2] The first sentence is already problem:

> "Every day, the world population increases of more than 200 000 people… In 2050, our planet will credibly count more than nine billion terrestrials!"

My house, my planet... and I! is an educational project in sustainable development, intended to make teachers, children and parents sensitive to environmental, social and sanitary aspects of the habitat. But why begin with the demographic aspect of this question? Is not this proposition connected to a Malthusian vision[3]? Apparently, writers ignore this Malthusian and scientistic dimensions of the problem –or want to ignore it, as it is very surprising to ignore this question since William Godwin's (1756-1835) work in 1820[4]. But, at first, writers accept the old Paul R. Ehrlich's conclusion –in 1968, in his famous book, *The Population Bomb*[5]. Or, maybe they know of the film *Solyent Green* (1973) which explains the same dark vision of the future[6]. Secondly, they agree with this kind of scientistic ecology "for the elite": "scientists know what is good for you". So we can see that the implicit values are really ignored or, worse, concealed.

Now, we must be honest; these values raise a big problem in a classroom. We have to inform teachers and on-line resource providers about these non-scientific dimensions of a scientific problem[7]. And we must admit our objectives, difficulties and *a priori*'s.

Knowing history of science to teach science

At first, we think that history of science –and there, history of biology– helps pupils and students to understand scientific inquiry, and maybe the links between sciences and society. Therefore, it is necessary to show the link between the history of science, philosophical history and economics of European society at the begining of the story, when the Scientific revolution of the 16th and 17th centuries took place.

The science that currently dominates was born during the struggles between Western Christians of the 16th and 17th centuries. After these philosophical wars, an economic vision and rationalization of the world will be placed above all other societal issues and will be confused with "progress". These struggles constitute the founding trauma of both the West and the science we practice. Faced with these endless, philosophical and deadly struggles, states and governments which were

being formed will almost imperceptibly drag the stakes of these struggles to another area of the "city life", a sector purportedly more neutral, objective, pragmatic and rational, and hence less so-called "ideological": trade. We are still far from the nineteenth century nations and the economic powers of bankers, but they are beginning to emerge and to become essential for human survival. In order to ensure civil peace and their own survival, the leaders of the time, by a sort of unspoken agreement, will place the "economic vision" and "rationalization of the world" above all other societal issues. States place themselves above the philosophical fray and ensure the freedom of some encroachment by that of others, a kind of moral neutrality and prosperity virtually universal (at least in the future). The "soft business" of all with all saves the Christians in their fight to death. As Voltaire said later, "When it comes to money, everyone has the same religion." Thus, only commercial competition shall be allowed and valued; first among individuals and between groups, countries and, soon, whole empires. But this fight will be considered positive, rational and pragmatic. It may even participate in people's happiness and help invent and illustrate the famous positivist "progress". The only valid and real criterion will be its effectiveness. Success and wealth will be the reward for the best of us. It is within this context that the so-called "Western science" will develop. It will therefore be marked from birth by an ambiguity still not assumed and mostly little known in its two main objectives: understanding of nature to escape his tyranny (slow understanding and motivated by an often altruistic and universalistic concern) and control to draw profit (profitability, immediate practical applications and technology). In both cases, it's about being efficient. It's in this concern for efficiency –and above all economic efficiency– that modern Western science will develop.

But, if we only give teachers resources without theses explanations, it is necessary to make five big bets:

- Pupils and teachers can understand historical texts, drawings, models or experiments (and sometimes only their telling);
- They can understand from current theories the most famous in biology: Evolution and Ecology theories;
- They can understand the complexity of these theories;
- They can rebuild the inquiry conducted in their elaboration;
- They can understand their moral implications.

But, and it may be the most important for us, we must take care because historical resources available to biology teachers could quickly cause problems in classrooms. And there are already problems.

A second example about Linnaeus' classification

We will show you a second example about the Evolution theory and the place for humans in the classification of animals. In 1994, Charles Darwin's Theory of Evolution appears for the first time in France in the biology syllabus. A few years later, it is already forgotten. Teachers prefer teaching facts and evolution mechanisms rather than the evolution theory because –so they say– students had many questions about values, moral and religious implications, and teachers didn't know how to answer[8].

Students ask questions about religion, creationism, social Darwinism, Malthusian theory, racism and eugenicist vision of society[9]. Teachers say "these questions are not biology." And they are right: teaching biology with history resources is more difficult than we expected.

For example, when teachers tried to study some historical texts, they encountered new difficulties, as classical texts were very hard to teach without some knowledge on history of biology and on general history. We want to show a very classical (but rarely known) text written by Carl Von Linneaus (1707-1778): *Systema Naturae* (1758), a book that we can find on the web.

Biology teachers wanted to read it to show how scientists saw classification in the eighteenth century, and they had a huge surprise.

At the top in nature was, of course, the human being. But, first surprise, there are two human species: the human being and *homo troglodytes*[10]: the orang-utan. And, second surprise, people in our species were more often divided according to culture, religion, customs and other such features.

[9] FERRIERE, Hervé, L'homme, un singe comme les autres, éléments d'histoire des sciences et d'épistémologie pour enseigner l'évolution de la lignée humaine, Vuibert Adapt, 2011.

[10] He also briefly described a *second* human species, *Homo troglodytes* ("cave-dwelling man").

Mammals, Primates. Antropomorpha.

1°) Homo sapiens. Diurnal man. «Nosce te ipsum.» Endowed with reason, talking, standing and bimane To distinguish from Homo ferus, Wild man, four-footed, mute and hairy.

2°) Homo troglodytes. Night man or cave-dwelling man.

Linneaus proposed 5 *taxa* of a lower rank: *Americanus*, *Asiaticus*, *Africanus, Europeanus and monstruosus*[11]. These categories were based at first on place of origin and secondly on skin colour[12]. Whereas Linné used some physical characteristics in his division, he also wandered about attributing characteristics according to his view of social and emotional features. He also divided human being by how he thought they were governed: by customs, caprice, opinions and laws.

Americanus are reddish (or copper coloured), stubborn or obstinated, merry, easily angered and free. They have black, straight, thick, hair – wide nostrils– harsh face. They paint themselves with fine red lines, and are regulated by customs. The *Europeanus* are white, sanguine and brawny. They are gentle, acute and inventive and they are governed by laws. The *Asiaticus* are avaricious and easily distracted. The *Africanus* are phlegmatic, relaxed, negligent and governed by caprice. And, finally, we discover a strange category: *Homo monstrosous*. There we find: *Patagonian giant* or the *Dwarf of the Alps*, the *Monorchid* –who has only one testicle– or the *Macrocephalus* of China and the *Plagiocephalus* (or "flathead") in *Canada.*

We can see that the text contains many "clichés" that still exist today. Also, we can only see "racism"[13]. In fact, students always see "racism". But at the time of Linneaus the word "racism" did not exist with the modern meaning. For example, the word "racism" is found only in 1932 in the French Academia dictionary. Linneaus does not intend to talk about superiority or hierarchy[14].

In the classroom, the debate that will follow this reading has nothing to do with the question of scientific classification of animals and the human being. To summarize, there is a high risk of making mistakes and non-sense in the classroom by reading a text without explanations or information about its values. So must we forget it? Of course not.

First, this text is but a step in a scientific process and, second, this step has moral implications. But often, students do not understand that sciences only give us knowledge and means to understand the world. Sciences don't give us moral values.

The transformations of moral values in history

If we want history of science to help understand the Inquiry Based Science, it is of course necessary to know the scientific concepts and investigation methods, but also the transformations of moral values and word meanings in time. The resources that we want to give, should show this complexity, and the values have to be clearly identified. Values, representations and implicit assumptions must be shown, and it requires a sharp, meticulous and balanced work before presenting these resources. So when we want to offer on-line resources in history of biology, we have to discuss about this sort of problem. Teachers need help specially in biology because the study of life –its fragility, history, links with the environment– affects us directly, and because all these objects involve values.

So how can we help teachers to use this means? First, we must talk about these values and not deny them. Second, we must give a very "rich backdrop" of scientists work and scientific process. We must give them a large background, backdrop or a rich historical context! It's not enough to suggest only some "scenarios" for classroom.

A last English example about Darwin

We can consider the Web quest on the site of the British Museum. There are biographies of important characters: Charles Darwin (1809-1882), Alfred Russel Wallace (1823-1913), Thomas Henry Huxley (1825-1895) –Julian and Aldous Huxley's grandfather–, ... We find some links with Scientific Explanations and examples about the evolution process. Authors offer interesting investigations but, soon, these resources also pose us some questions. There is a short presentation of the

context in which Darwin worked (some pictures of the period and just a few words). The author's present, "Victorian England" with its Imperial power and England as a "trading and religious" nation. But what does that mean? Why show only one economic aspect: a "trading nation"? What about the industrial revolution and colonialism? In fact, it's difficult to understand what "Imperial power" means exactly. And what about the emergence of capitalism? What about the links between sciences and economy? And what about the Malthusian vision –which still exists today– and the hierarchical view of population? And, for example, what about the Sepoy War in India in 1857, while the famous Darwin's book is published in 1859? Why show only the religious aspect of the controversy?

Is it a choice to reduce the debate between science and religion? And we face the challenge posed to teachers: religious values, as if they were the only ones that can interact with science. It's an artificial issue and also a deliberate choice. But it is not enough to really understand this controversy. And this presentation only partially addresses students' questions.

We see that the work of historians is necessary here: biology teachers should be able to quickly have a fairly complete historical context. We must therefore speak about the general context of science process. We must speak about moral, social, economic and political construction of theories in biology to understand them better. Not because the context explains the science content produced, but because the context explains how Darwin's theory was perceived, received and translated far away from science. How his theory became a political speech, a social *a priori*, as, for example, with "the struggle for life". Sometimes, people have kept only the speech about values and not the scientific data: they believe that social and political conclusions are directly inspired by scientific laws.

When we teach the evolution theory, we only keep the data and forget the values speech, while students have to face this speech when they leave school. We must "draw the historical scene" as rich as possible, and see exactly the real biological questions that arise. We must not deny all the issues that biology can address. But after the exposition of these issues, after showing their links with the biological question, we must explain that science does not answer all the questions. Science does not answer questions about values. They talk about reality and not what we think good or bad in our life, our history and our society.

Abstract

The role of History and Philosophy of Science for Science and Mathematics teaching has been a theme of several studies about a correlation of these three areas, particularly with the explicit relationship between history, philosophy and cognition.
Our research is inserted in the context of development of theoretical references for the creation of instruments to improve the learning of concepts and theories in Science and Mathematics. We believe that such creation must be in a structured, articulated, and integrated mode for achieving analytical learning.
Our first and main report involves identification and characterization of scientific models by historical-philosophical reconstructions, which presupposes the overcoming of that modeling –a proto-theory– for obtaining a universal theory. As an exemplar of analysis and findings, we present an application to the study of Beta decay (first identification of nuclear weak interaction) addressed to undergraduate physics students or in-service teacher education. This exemplar illustrates some pedagogical results of the application of this proposal in a discipline for undergraduate students of a physics course at State University of Londrina, Parana, Brazil. The second part of our work brings a synthesis of findings in several researches, characterized in two axis of investigation: in partnership with graduate students of our research team, and on the scope of a graduate program in Science and Mathematics Education at the same university.

[1] Research funded by Capes, CNPq and Fundação Araucaria, from Brazil.

The role of History and Philosophy of Science (HPS) in Science and Mathematics Education (SME) has been a theme of several studies about a correlation of these three areas, particularly with the explicit relationship between history, philosophy and cognition.

There are two traditional perspectives in these studies. The first one considers that historical reconstructions (with epistemological cares) or historical-philosophical reconstructions constitute accomplished contributions in the area of SME, since they present indications of their potential use. The second considers those reconstructions as a research stage, which should be followed by adaptations and even pedagogical transformations; then they would reach the status of scientific outcome.

The latter perspective has, yet, two axes. One considers that investigation of the process to articulate, structure and integrate history, philosophy and pedagogical knowledge is already a scientific result, since it presents a theoretical-conceptual-methodological analysis of the produced proposal. The second axis takes into account the investigated process, but considers only as resulting scientific reports the empirical findings obtained from the application of this process.

Our research is inserted in the context of the development of theoretical references for the creation of learning condition for concepts and theories in Science and Mathematics. We believe that such creation must be in a structured, articulated, and integrated mode for achieving an analytical learning.

Our ongoing studies aim to demonstrate that involving the philosophy of science in a correlative field requires knowledge and commitment with a balanced relationship between scientific subjects, theoretical-methodological referents, and application context. In the historiography of science, another related domain, development of historical reconstructions involve a theme in a historical period, with the indispensable care for reliability and intelligibility in the interpretations of primary and secondary sources.

Therefore, when one is making an investigation that approximates, connects, and articulates knowledge domains with Science Education, one should take in consideration at least the epistemological, methodological, and ontological assumptions. It is a careful and rigorous process, which cannot contain conflicts and inconsistencies in the interdisciplinary knowledge production.

However, there are some issues:

- What is the role of HPS in the development of this process?
- What is the public of an educational and formative action?
- How to develop an approach to reach our goal of teaching and learning about a scientific culture?

These mottos expose a very clear point to us: it is not enough, despite being necessary, to build historical reconstructions, or studies of philosophy of science, or even explicit historical-philosophical debates, to contribute to the knowledge production in the area of Scientific Education. We cannot confuse the Teaching of Sciences with Teaching of History and Philosophy of the Sciences, and the same applies to scientific investigations of those areas.

With this understanding, we have been developing research in the Graduate Program in Science and Mathematics Education, at State University of Londrina, Paraná, Brazil. This research has as central focus the search of scientific outcome that corroborates an interdisciplinary integration of the domains of History and Philosophy of Science with the domains of Scientific and Mathematical Education.

In the following synopsis we present exemplars of consolidated findings, obtained from our investigations or in partnership with advised graduate students, organized in two axes.

Axis of Research: Investigation of Historical and Philosophical Approaches for the Teaching of Scientific Knowledge in Basic Education

"Historical-philosophical Approach and Mathematical Education –A Proposal of Interaction among Domains of Knowledge"
(BATISTA, I. L., LUCCAS, S., 2004)

We present a historical-philosophical approach with the aim of contributing to research in Mathematics Education, based on analysis of epistemological, logical, ontological, and methodological elements of the structure and the articulations that a specific knowledge presents, from its creation until its current use in Mathematics Education. Additionally, we are concerned with the knowledge ability to solve mathematical problems, as defined by Larry Laudan. Based in theoretical references in History and Philosophy of Science and Mathematics, we provide an exemplar of application of our approach, with an historical-philosophical reconstruction of the subjects Systems of Linear Equations and Determinants, found in the works developed by two mathematicians: Takakazu Seki Kowa (1642-1708) and Gottfried Wilhelm Leibniz (1646-1716).

"Investigation of a Didactical Sequence with Historical-philosophical Focus for the Teaching of Trigonometric Functions in High School"
(SAMPAIO, H., BATISTA, I. L., 2007)

In this research, we investigated the process of construction of a historical-philosophical approach through a historical synthesis about Trigonometry, through documental research in books of History of Mathematics, especially the ones that specifically deal with the History of Trigonometry. We adopted a qualitative methodological approach, with the aim of investigating the construction of a didactic sequence, based on the historical synthesis of Trigonometry, focusing mainly in the study of trigonometric functions and its teaching in High School. We introduced a philosophical approach that incorporates an axiological discussion, constituted by a group of cognitive values of Science, and applied it in Mathematics Education. The historical-didactical sequence, based in Didactical Engineering and Meaningful Learning, was applied in the second year of High School, in Londrina, Paraná, Brazil. Our findings showed that the built approach was effective for trigonometry learning, making manifestation of cognitive values in Mathematics possible in the historical-didactical sequence and in the students' knowledge.

"A Historical-pedagogical Approach for the Teaching of Sciences in the Initial Series of Basic Education"
(BATISTA, I. L., ARAMAN, E. m., 2009)

This research, of qualitative character, promoted the integration of references in the elaboration of an appropriate historical-pedagogical approach to the initial series of Basic Education in Londrina, Paraná, Brazil. The reference frame contemplates the need for Scientific Literacy; Meaningful Learning through innovative activities in Science Teaching; elaboration of Conceptual Maps by students; and construction of activities that respects the children's cognitive development. The theme for that investigation was the Rainbow and its understanding in Physics. We elaborated a reconstruction of the historical episodes from ancient Greece until the physical understanding of this phenomenon in the 18th century. From this reference frame and the historical study about the phenomenon, we created a historical-epistemological sequence of experimental activities that was applied to students of fourth series of Basic Education. Evaluation of the learning process was done through elaboration of Conceptual Maps by the children, before and after application of the sequence. Our findings evidence that the construction of a historical-pedagogical approach to the learning of physical concepts in Basic Education is valuable, providing good outcomes in that teaching level.

Schema of integration of references

Scientific Literacy

(Execution, registration and analysis)

Cognitive Constructivism

Axis of Research: Teachers Knowledges and Interdisciplinary Focus

On the Perspective of the Education of Teacher and Researcher in Sciences

Findings of our research on the Education of Teacher and Researcher in Sciences have been indicating the significance of the use of HPS, as both formation and qualification search for some intrinsic aspects as described below.

In the initial training to disciplinary research, HPS focus is intrinsic to the preparation for:

- Creative research.
  A critical, non-dogmatic, contextualized, and opened view to innovation is necessary with a balance. An open mind without criticism could go to fantasies or senseless ideas. A critical mind out of balance could become intellectually sterile.
- Methodology and planning of research.
  The researcher becomes "blind" without a historical view of a science and without the dynamics that the proposed scientific problems present. In this way, one can only choose a research line by imitation, by blindly adopting the orientation of some group, or by following the trend, or just the *status quo*.
- Elements of decision.
  HPS provide access to structural difficulties, fruitful tendencies, clear and delimited objectives.

- How to inquiry.
  With this ensemble of elements, a rational and fertile decision about what to do in a scientific research is possible.

On the Initial Education of Teachers

It should integrate the elements listed above for the researcher and, complementarily, realize that the teacher is an investigator of her/his pedagogical practice. In addition, the didactical materials with historical-philosophical fundaments should suffer adaptations and pedagogical transformations before an application in classroom to obtain good quality results.

With this kind of education, the teacher should know how to implement HPS approaches in the teaching of each science. Approaches work with, for instance, reproduction of historical experiments or provide familiarity with the original scientific sources. In addition, some processes that transform a historically constructed knowledge in school knowledge, and that integrate HPS systematically in the school knowledge.

According to our findings, such a teacher should know and investigate:

- specific activities of HPS;
- references (theoretical-conceptual and methodological) for class preparation;
- didactical reconstructions of historical experiments;
- interdisciplinary activities, differentiating a specific scientific knowledge from educational knowledge.

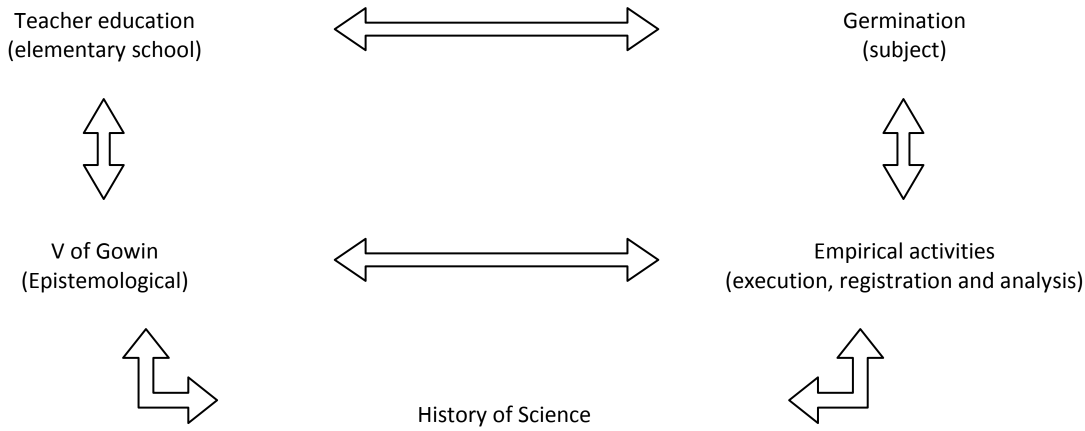
The literature in Science and Mathematics Education has demonstrated that with the current didactical and practical education of science teachers, few are empowered with these competences (TARDIF, 2002; BATISTA, 2004 and 2007). This indicates the requirement of curricular changes and an update of academical culture of the undergraduate courses and in the teachers updating who are in service. It is a new knowledge (disciplinary, methodological and interdisciplinary) to the teacher. Consequently, the focus needs changing in the styles and evaluation methods, and that has to be significant to the students. As all innovations, some unexpected institutional difficulties will probably appear, as it happens for any other approach different from traditional practice in undergraduate courses.

Exemplars of Teaching Scientific Explanations Using a Historical-philosophical Structure

"The History of the Science and the V of Gowin in the Science Teachers Education"
(NASCIMENTO, E. G., BATISTA, I. L., 2007)

It was an investigation about the construction of a proposal for initial education of teachers to science teaching in the first grades of Basic Education, in Brazil. From the references frame, we identified some needs for scientific literacy, and the Meaningful Learning suggests the use of innovative proposals to the discipline of science in this level, with the use of learning facilitators. Our proposal is based on an approach that includes the use of History of Science associated with experimental activities. Also, it includes Science Teaching research, with Gowin's V as a way of structuring the activities (implementation, registration and analysis). The theme chosen for this study was the seeds germination, and a synthesis was elaborated of historical episodes necessary for its understanding. Oriented by such synthesis and references frame, we developed and applied an historical sequence of activities to groups of senior students in an undergraduate course of Pedagogy. The monitoring of activities and the learning results was through analysis of V´s Diagrams constructed by the students themselves during the activities. The research results allow us the inference that this approach, when used in an appropriate manner, can become a significant tool in teachers education of the early grades of basic education.

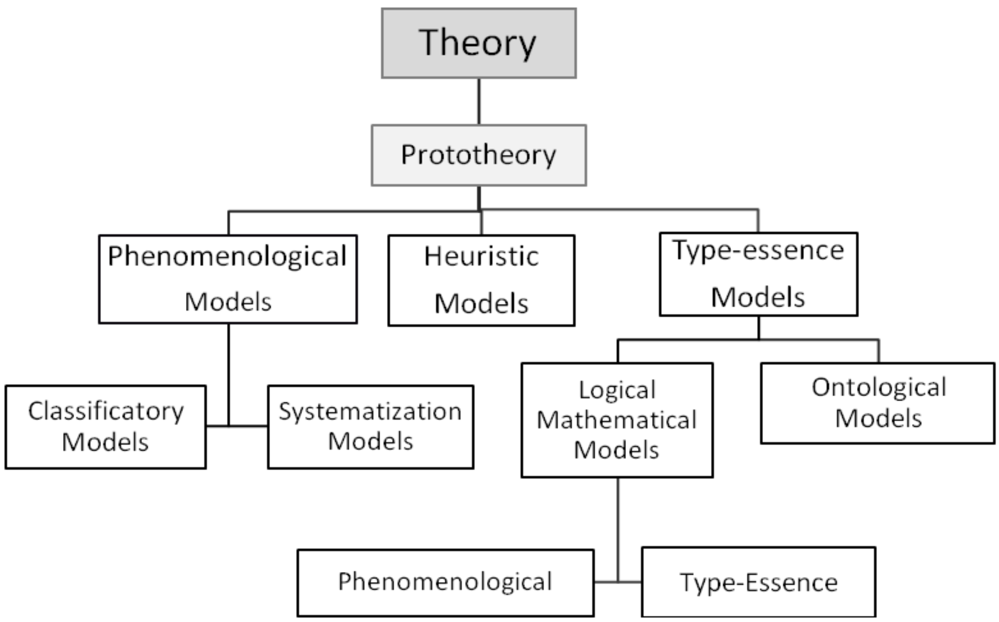
Schema of integration of references



"Undergraduate Discipline of Evolution of Concepts and Theories in Physics –The Routes of Theory Building"
(BATISTA, I. L., 2004 and 2007).

Our main report involves the identification and characterization of scientific models by historical-philosophical reconstructions, which presuppose the overcoming of modelling –a *proto-theory* (BATISTA, 1999)– and achieving a universal theory. As an exemplar of analysis and findings, we present an application of the historical-epistemological study of Beta decay (first identification of nuclear weak interaction done by Enrico Fermi, in 1933) addressed to undergraduate students of physics or in-service teachers education. This exemplar illustrates some pedagogical results of the application of our proposal in a discipline for undergraduate students of a physics course at State University of Londrina, Parana, Brazil.

Understanding the construction of theories: a *Theory Schema* (1999)



Definitions and explanation of the schema:

- Model:

  "[...] a model is a natural or artificial entity related, in some way, to the entity under study or some of its aspects. A model is able to replace the object (entity) and to serve as a relatively independent "quasi-entity", producing certain mediated knowledge concerning to that entity." (BATISTA, 1999 and 2004)

- Theory:

  "[…] is an explanation that is consistent with related empirical aspects, in a greatest scope, to explain the experimental data already known and any other forthcoming. It must be consistent with a chosen logic, classical or heterodox, with a syntactic structure (mathematical and/or linguistics), with the domain of applicability and with a set of rules that allow to connect the syntactic structure with the empirical domain."(BATISTA, 1999)

Building theories from models

Depending on the expression of the nature of the entity to be modelled, we judged advisable to split the heuristic models in phenomenological models (they describe certain aspects that characterize the way a physical process grows, but it doesn't explain precisely why it happens) and essence-type models (it supplies some preliminary interpretations of the essences and causes of the physical process as well as a mathematical structure).

Phenomenological Instance

Phenomenological models include classificatory, pictorial, and linear analogical models; they are typically empirical models. They apprehend regularities in specific relations of studied entities. However, they are not able to explain their essences (ontology, logical structure and syntax).

Type-essence Instance

These models provide a preliminary interpretation made by analogical hypotheses and generate ontological, causal and logic-structural formulations of a process in analysis. (BATISTA, 1999, p. 29).

Type-essence models are split in:

- Logical-mathematical

  "[...] are systems of logical elements, whose mathematical structure is analogous to the structure of physical entities. If they have such structure in a lower grade, they are called phenomenological logical-mathematical models; if they have it in a higher grade, they are called logical-mathematical type-essence models." (BATISTA, 2004, p. 468)

Logical-Mathematical elements can be translated as a logical-syntactical one for a possible application in different phenomena and/or different domains. We can figure out a formal representation –mathematical, linguistics, algorithmic–, whose structure guides and clarifies a concept in development. In this case, the rules of the linguistic structure become the rules of a scientific explanation. For example, the conservation of algorithmic properties represents and translates the conservation of natural properties of organic, geological, chemical systems. Each algorithmic manipulation, that is, an action in an equation system signifies a manipulation of the system itself.

- Ontological

  "[...] they are assumptions regarding to an essential peculiarity (about what exists) in domains of physical reality. Recognizing these peculiarities of real is to achieve relevant theoretical results." (BATISTA, 2004, p. 468)

Heuristic Instance

These models consist of a synthetical combination of certain explanations coming from phenomenological and type-essence instances, but still analogous to some previous scientific knowledge. They are a partial and phenomenological solution of the modelled problem.

However, we work to identify and to analyze Universal Theories. In this process, we create a way to supplant that profusion of model concepts found in literature and, mostly, to explain the transition and achievement to a well-established theory, an answer about what is the bridge between models and theory. We created the concept of *Proto-theory*, which is an early and intermediate epistemological stage between models and consolidated scientific theory. It becomes a new, original pattern and an underpinning to create new models for empirical and theoretical tests. It is needed to consolidate the new theory indicated by a proto-theory in a process of confirmation, universality, and improvements.

Proto-theory: scientific creation that is originated from a quite innovative and synthetical solution (general hypotheses, principles, new physical constant and new mathematical/syntactical structure) to problems enunciated by heuristic models.

For the explanation of Beta interaction, that probed itself as weak interactions between elementary particles, it has a phenomenological instance and a type-essence instance in the base of its construction, as well as the epistemological elements to ripen and become a (consolidated) scientific theory.

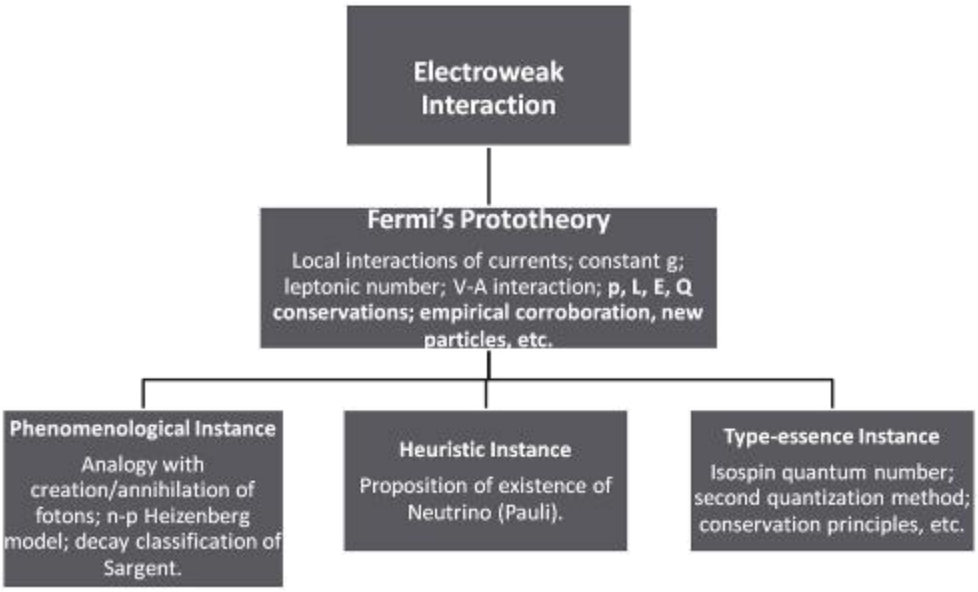
In the phenomenological instance, classificatory models are present and already systematized. In the essence-type instance, superior logical-mathematical models, whose mathematical structures are in analogy with the structure of physical entities, participate and produce ontology to the entities in study.

As a transition between investigation of the built model and the consolidated formulation of a new phenomena, it does not have a previous analogous solution in the same scientific domain and it is the beginning (*proto*) of a Universal Theory.

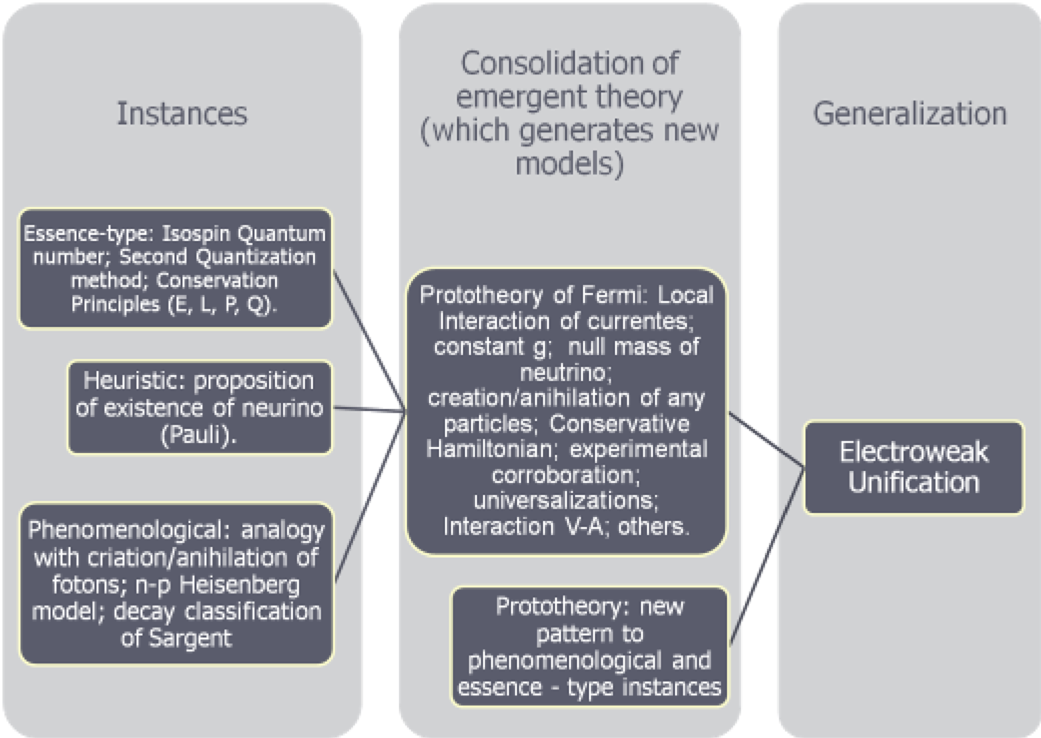
Differentiation between the proto-theory and heuristic models: in opposition to these last ones, which are a mediated intellectual acquisition of the unknown via another known entity, the proto-theory proposes quite new conceptual elements, reported with a new language and new ontology. These elements must be empirically confirmed, and they can be supported by a multi-valued logic, para-consistent logic, etc, having as consequence a new theory.

As a proto-theory, Fermi's elaboration showed originality, heuristic force and effectiveness. In addition, it showed deficiencies and limitations that implicated new improvements from theoretical to empirical studies in Physics. First, Fermi's proto-theory contains inconsistencies according to the classical logic, once it unites relativistic (leptonic current) and non-relativistic (nucleonic current) approaches. Second, in the theoretical structure, we found physical problems because the coupling constant is not renormalizable. However, in spite of its limitations, it is a good answer to the experimental results in low energy (about 300 MeV).

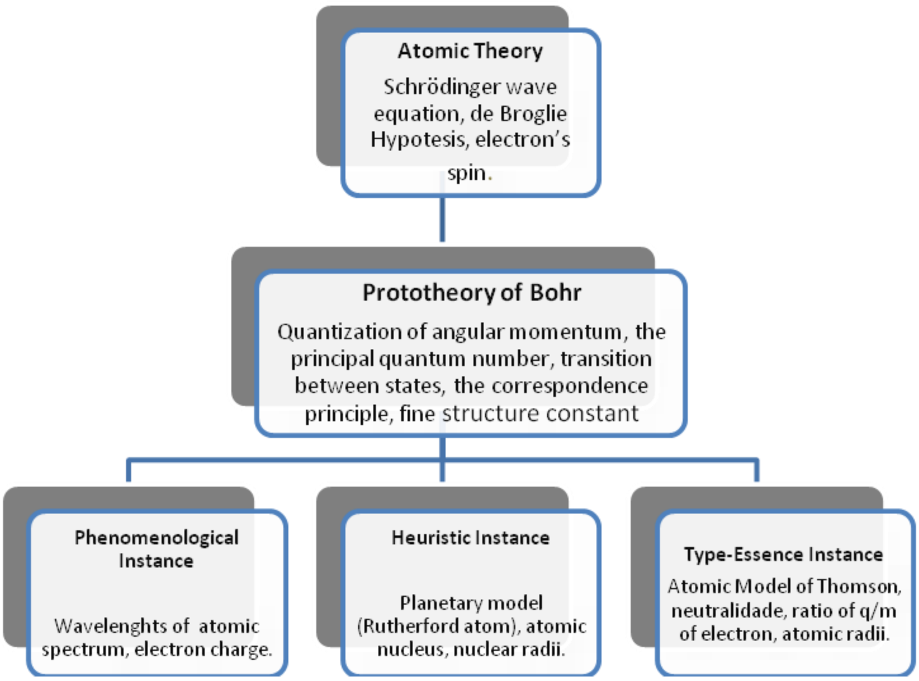
From the Called "Universal Theory of Fermi" (BATISTA, 1999 e 2001):
using an epistemological exemplar to undergraduate course of Physics



From the past to the future



Exemplar produced by undergraduate students after historical-epistemological studies of the schema and applied to Atomic Theory



About the Adoption of the History and Philosophy of the Science in the Development of the Interdisciplinary Knowledge of Teachers

With the incorporation of epistemological analysis and the critical exam of the History of the Science, we are looking for consistent bases, mainly if we want to understand the process of change of scientific knowledge. The Historical-philosophical approach of the Sciences, as a powerful instrument for transformation of educational practice, collaborates with the construction of educational and school knowledge. There are some justifications for such statements:

- Transformation of common sense, of the *doxa*, to a scientific justification, an *episteme*;
  The understanding of concepts, theories and scientific explanations is advisable to aknowledge their history by teachers. Without such understanding, the teacher usually organizes the content mostly without a context, sometimes reproducing graphic representations, symbols and mathematical process without meaning. Other times, this happens with an ingenuous view of experience in the development of a scientific explanation.
- Professional practice begins with the construction of an identity in the educational action;
  The teacher concerned with the History and Philosophy of Science is able to build bases for her/his educational practice. In other words, is able to think it and indeed to transform it, mobilizing her/his knowledge to the construction of educational knowledge. Thinking critically demands a philosophical position from the teacher, and it enables her/him with an epistemological position before the debates and impasses that exist in the studies of the philosophical conceptions of Science. For Kragh (1987), nobody knows a science in full while he/she does not know its History.
- Interdisciplinary production in the contents, providing examples to use at classroom;
  During the historical-epistemological studies of some subject, we observed the dynamical process of evolution of such knowledge and its importance to other sciences. Frequently we do not know how to use concepts in a multidisciplinary or interdisciplinary context. With an approach from the History of Science, the connections and the integration between disciplines reveal themselves spontaneously along the process of the construction of knowledge.
- Promotion of debates on cognitive values of the science;
  There are several areas of philosophy that can be studied, as epistemology, aesthetics, and logic, among others. The cognitive values from axiological studies of science are good sources and appropriate to the themes and contexts, basing discussions in order to promote scientific activity. Axiological studies enrich the education of the teacher once they enable him to understand, for example, the universality degree of a theory and its priority in teaching.

From an understanding of the evolution of sciences and their implications in human culture, the teacher assumes an investigative attitude and transforms a class into a creative atmosphere of new perspectives in sciences.

And research continues...

In conclusion, we sustain the need of continuous research regarding educational knowledge, in initial and in service education of teachers. As well, there is a need of investigated constructions of interdisciplinary approaches, integrating historical, philosophical and didactical studies, which will provide references and justifications, in a contemporary form, to the presence of the History and Philosophy of Science in Scientific and Mathematical Education.

Our findings has shown that the debate regarding historical-philosophical facts as a means of understanding scientific conceptions, looking at the problem of the nature of scientific knowledge from differentiated focuses, is capable to foment a differentiated educational practice. We have demonstrated that they contribute in a significant way to the development of a school knowledge recognized as interdisciplinary, and as such, it should be learned.

UNDERSTANDING OF PRE-GALILEAN MOTION TRAJECTORY BY PRESENT DAY STUDENTS. CAN AN ANCIENT OBSTACLE BE OVERCOME BY OUR STUDENTS?

Marina CASTELLS, Aikaterini KONSTANTINIDOU
Departament de Didàctica de les Ciències Experimentals i de la Matemàtica,
GRIEC, Universitat de Barcelona, SPAIN
marina.castells@ub.edu

Abstract

A group of pre-service students answered two problems regarding the motion trajectory of a body which falls down, or is thrown, from moving vehicles. Problems were qualitative and in an everyday context. Written answers by students from two different educative levels were analysed, identifying ideas and arguments. Their summary is presented building Systemic Networks. From these networks, and considering the relationship among several of their categories, we can infer students' main difficulties and conceptions related to the comprehension of some aspects of Galilean Relativity, in particular about the motion trajectory relative to different Galilean Frames of Reference. Results show that a non-small group of students understand velocity and trajectory of a body as an absolute magnitude, and give explanations similar to others found in History of Science. A comparison with pre-Galilean understanding will be presented, especially with T. Brahe's, Copernicus', G. Bruno's and Kepler's interpretations. Didactical implications of these results will be commented.

Introduction and proposal

In today's context of science education, we consider that students arrive at school with a background knowledge that, for them, is undoubtedly valid and powerful enough to interpret their surrounding world. Based on the research of students' conceptions in science, we know that part of this knowledge is in conflict with scientific knowledge, and some students are reluctant to reconsider what they think they know. Beside knowledge of these students' conceptions, knowledge of relevant episodes in the development of science can help better understand students' thinking and some specific difficulties that students have in relation to some Physics' topics (Saltiel, 1978, Castells & Konstantinidou, 2008).

A research about students' ideas related to motion trajectory, related to different Galilean frames of reference (henceforth FR)

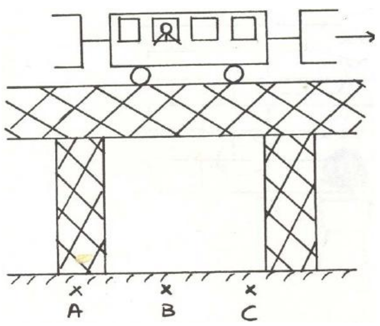
From a wider research on students' conceptions and difficulties in the comprehension of Galilean Relativity (Castells, 1998), and from other researches on students' ideas and reasoning related to this topic (Saltiel, 1978, 1980; Aguirre & Erickson, 1984; Lie et Al., 1985), we identified the main difficulties students have in relation to Motion Relativity. Saltiel (1980) thinks that the results obtained could be well accounted for the existence of an organized system which she called the 'Natural model' as opposed to the 'Kinematics model of the physicists'. The study of Panse, Ramadas & Kumar (1994) and Ramadas et al. (1996) identified students' ideas related to Galilean Kinematics. A common conclusion is that there is a Pseudo Relativity in the students, in which magnitudes are not considered relative to a FR, and that the FR notion is near to the object notion, along with properties of specific objects. McCloskey (1983) and Whitaker (1983) focused mainly on the students' difficulties related to an object trajectory of drops from a carrier in motion.

In the specific study we present here, we focus on ideas about the motion trajectory relative to different Galilean FR's.

Information is collected from the written answers of individual students to two problems which are very similar from the Physics point of view.

The sample are students from Primary Education Teacher Training (124) in the University of Barcelona from three levels: Science 3rd course (51), Science 1st course (28) and Non-Science 1st course (45).

Problem 1: A train passes through a bridge below which there are some workers making several arrangements. There are three groups of workers a little apart among them. An object falls down from a boy on the train whose hand is outside the window. If you were near the place where the men were working and you were afraid that this object could damage them,



Direction of the train's motion

Which group would you warn?

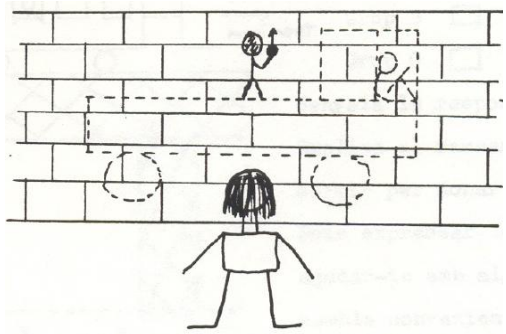
Group A

Group B

Group C

Mark your answer here and explain your reasons for it. You can express your answer either in words or with the help of a drawing, if you consider it more convenient.

Problem 2: A boy is playing on the platform of a lorry that moves at constant velocity. The lorry passes behind a wall which completely hides if from an observer on the other side of the wall. While the lorry passes behind the wall, the boy throws a ball up vertically.



Direction of the lorry's motion

a) Draw and explain the trajectory that the ball will follow from the perspective of the observer on the other side of the wall.

b) Do you think that the ball that has been thrown up by the boy will fall down back to his hands? Explain your reasoning.

Are problems similar to the ones proposed in our research discussed in ancient times of science development? Our problems are related to the history of acceptation of the Earth motion, which was not accepted in the ancient Ages, and as we know from HC, it was a very big "epistemological obstacle" to overcome (Bachelard, 1939). So, we will revise in the following paragraphs some points of the historical development of the Relativity Principle; the summary will focus mainly on the case of the acceptation of the Earth motion and of the trajectories relativity.

Some points of the History of Galilean Relativity that relates to our research on students' ideas and conceptions on this topic[1]

In the most ancient times Aristotle and Ptolemy (and Aristotelians) defended the impossibility of the Earth motion with some arguments from observation like: 'objects dropped from the upper part of a tower or from the ship's mast arrive to its foot', 'the object thrown vertically up from the Earth or from the ship's deck arrives to its base', 'clouds and birds, and objects and buildings on the Earth are not thrown away'.

Nicolaus Copernicus (1473-1543) in his book *De revolutionibus orbium caelestium* (1543) presented the cosmologic model with the Earth revolving around the sun and on its own axis. Copernicus reasons in terms of 'natural motion'; to Copernicus, this is obvious, and needs no demonstration. With the idea of participation in the Earth's motion, Copernicus could explain why we see things falling vertically from the top of a tower; he said we cannot notice the motion of these things, like the Earth motion, because we participate in the Earth motion too.

But to Aristotelians and to Tycho Brahe (1546-1601) this reasoning was weak. They asked: "Why do these two natural motions (the falling down motion and the one like the Earth motion) not disturb each other?" To Aristotelians, a body can only participate in one natural motion; it was like an accepted truth. It was Brahe who proposed the famous experience of the cannonballs, and proposed it in order to demonstrate the impossibility of the Earth motion, but he looked for a more 'modern' example, more of his days (the cannon was a recent invention in his time), than the ones that had been repeated for long from Aristotle and Ptolemy. Brahe (1592) proposed this new example answering Copernicus' argumentation saying:

> "…but what will happen, I ask, if a cannonball is fired to Orient with a big cannon and from the same place another on is fired to Occident? Can we think that the one as well as the other will run the same distance on the Earth?" (Tycho Brahe, 1592, *Epistolarum Astronomicarum liber due*, Uranieburg)

He didn't think this, and answered himself:

> "...By reason of the extremely fast Earth's diurnal motion (if it were), the cannonball thrown to Orient will never be able to run as much distance on the Earth, the Earth (because of its own motion) going ahead of it, as the one that, like the first, were thrown to Occident..." (Tycho Brahe, 1592, *Astronimicarum epistolarum liber*, Uranieburg)

Against Copernicus' reasoning, Brahe says that the 'natural motion' notion (in opposition to violent motion) doesn't admit a body with two different natural motions, and he adds that these two motions must disturb each other. With this thinking, Brahe follows Aristotle's ideas. Brahe doesn't accept the Copernican theory that states that any 'terrestrial' object must follow the Earth motion. He thought that, if it was so, and considering the cannonballs' motion caused by participation in the Earth nature, then, if the Earth was in rotation, the two cannonballs would run different distances in each direction, but because this doesn't occur, it means that natural motion by participation of the cannonballs doesn't exist, and the cannonballs only have the violent motion of firing. In fact, Brahe thinks about the motion of a body in an absolute way. As the cannonballs had, according to Brahe, their own velocity, independent of the Earth motion and the observer, the cannonball shot to Orient would be in disadvantage relative to the one to Occident because in the first case the Earth is moving in the same direction and in the second case in the opposite direction.

Giordano Bruno (1548-1600) went further than Copernicus and explained this participation in the Earth motion. He gave us the notion of Mechanical System (1584). This is 'an ensemble of bodies animated with the same motion, but it is as if this motion in which they participate did not exist'. Using this notion of Mechanical System, he could refute Aristotelian reasoning of clouds and birds against the Earth motion, and he explained why we see a body falling down vertically from the top of a tower and why a body thrown vertically upwards from a point of the Earth will fall vertically down to the same place. This is because they are part of the same Mechanical System due to their participation in a common motion. This notion of Mechanical System didn't have any meaning to Brahe and to Aristotelians. Bruno reached the following general conclusion:

> "It is impossible to recognize the motion of a Mechanical System from experiments made inside it". (Bruno, 1584, *The Ash Wednesday dinner, La Cena della Ceneri*, third dialogue)

Despite these ideas, Bruno didn't solve the problem completely –we could still ask why the cannonballs conserve the cannons motion in which they participated when they were part of the same Mechanical System. Bruno uses the notion of 'impetus' to explain this motion conservation, but this is an ancient notion; it doesn't lead towards the idea of inertia. We have to wait until Galileo. To Bruno, a body needs an action (impetus) to persevere in its motion. This is different from the

[1] This review of HC in relation to our Physics' problems is based on Koyré, A. (1939, 1957, 1961); Tonnelat, 1974; Saltiel, E. (1978), Bernardini, C. Ulisses Vol7 (1979) and some translations of books of the ancient scientists.

Classical Physics of Inertia. In summary, Bruno has a good appreciation of Motion Relativity, but he doesn't explain it enough. The notion of impetus cannot justify the notion of Mechanical System.

And now, only two words to situate Kepler's thinking. Johannes Kepler (1571- 1630) in some aspects goes backwards from Bruno. To him, the Mechanical System rests necessarily linked to a physical action. The separated bodies of the Earth don't follow it because are part of the same Mechanical System, but because there is a real attractive force between the Earth and these bodies (the Gravity force). The rock follows the Earth because it attracts the rock; this is not a mechanical state but a real physical force which is necessary to win the rock's inertia. To Kepler, inertia is like resistance.

In the *Dialogo sopra i due Massimi Sistemi del Mondo Tolemaico e Copernicano* (1632), Galileo Galilei (1564-1642) wanted to demonstrate the Earth motion, but he was not able to find arguments to prove it, so it was necessary, first of all, to refute arguments against this motion, specifically, that if the Earth rotated we would perceive it in everything. With this aim, he enunciates the general thesis that the common motion of bodies constituting a Mechanical System has no influence on the behaviour of these bodies in their relations between each other and so, this motion can't be demonstrated from this frame. We can find a very clear example of this thesis in Galileo's text from the Dialogues, 'From Venice to Alep' (Galileo, pp. 171-172), in which Venice, for example, and also Alep, can be used as a reference that doesn't participate of the ship's motion. For the study of the ship's motion, the Venice and Alep references, which are at rest one relative to the other, are equivalent. This will seem obvious to anybody, but for the study of the butterfly motion, referring to Venice or to Alep does not seem so obvious. Relative to Venice, anyone could say that the butterfly's motion is double: on a hand, it moves around from here to there, and on the other hand, it moves from Venice to Alep. Venice can be used as referential for both motions because it doesn't participate of any. But on the contrary, if we refer the butterfly motion to the ship, only the motion of moving around, which the butterfly doesn't share with the ship, can be studied. As for the other motion, the one shared by both the butterfly and the ship, it can't be studied in the ship reference, as it would result in 'nothing'. The question that we can ask, then, is the following: Do we obtain the same description of the butterfly moving around motion from the Venice reference or from the ship reference? Galileo's answer, which is not intuitive, is 'yes'. The reason is that the ship motion is uniform related to Venice, and this uniform motion, which is like 'nothing', doesn't make any change in the moving around motion of the butterfly. For the butterfly motion, both references in relative uniform motion are equivalent and will give the same description of the butterfly moving around motion. In this text, in fact, Galileo brings us the intuitive concept of FR, and the Classical Relativity Principle (Physics laws are the same in any FR that is moving in a uniform motion) are clearly expressed in another very beautiful and famous text also from the Dialogues (Galileo, 'The second journey', page 188).

Galileo uses the indefinite conservation law, uniformity and persistence of motion if no compulsion to stop it exists – the *Law of Inertia*– and the Relativity Principle. The thesis is that a motion is conserved, not because it is natural, but because it is *motion*. We know we can't assert that the Classical Relativity Principle is entirely due to Galileo, but it is still named the Galilean Relativity Principle. The limitation of Galileo's Inertia Principle to horizontal motions, which he considered on the Earth surface, transforms these horizontal motions into uniform circular motions around the Earth centre.

With this historical revision, we can say that the Classical Relativity Principle has been present in Physics long before it had been adequately formulated; it is not the discovery of a single man. The beginnings are due to Bruno, Copernicus, Kepler, Galileo and Descartes, who contributes to the Law of Inertia; followed by Huygens, Newton and Euler which in the 18th century recognizes the validity of the Relativity Principle to the entire field of Mechanics and even for the whole of Physics.

The analysis in our research

The analysis of the students' answers to the two problems previously presented includes two parts: 1) a deep analysis of the students' answers to each problem and 2) an analysis of comparison and relationships between the various aspects of the answers to both problems.

The problem to problem analysis begins with a **qualitative analysis** to the interviews we have done to some students and to the individual written answers. We try to establish some categories and subcategories, some of which may be mutually excluding while others may be produced at the same time. We collect this categorization structure using the Systemic Network technique (Bliss, Ogborn & Monk, 1983). After this qualitative data analysis, we perform a **quantitative data analysis** of both problems and its comparisons based on categories and subcategories of Systemic Networks.

1. Analysis of answers to problem 1 and problem 2

Because both problems are very similar from the Physics point of view, we will present the analysis of both problems together. At first, we interviewed two students immediately after they had answered the problems. Interviews have been of help to build the network from the written answers. We include and comment below some of the parts of these systemic networks that correspond to the big categories found in both problems.

The first big category is **Drawing**. Here we classified the students according to the **making or not making of a drawing** criterion, and according to the **type of drawing**. We don't present the network here.

The second category is type of **Answer** (problem 1 and problem 2), in which we classify the students according to the chosen answer. In problem 2 we also have the big category of type of **Answer to question b).** We represent here the systemic network of problem 2, which includes the network of problem 1 because the categories of the Answer to problem 1 are exactly the same of the Answer to problem 2a).

- Answer (Aa) problem 1 and problem 2a)
  - Vertically (Aa2)
  - Backwards (Aa3)
  - Two options (Aa4)
  - Not clear (Aa5)
  - No answer (Aa6)
- Answer (Ab) problem 2b)
  - Yes (Ab1)
  - No (Ab2)
  - No answer (Ab3)
  - Not clear (Ab4)

Fig. 1: Network of Answers to problem 1 and problem 2.

In our Teachers sample, the biggest percentage corresponds to the **correct** answer, but the percentages of **incorrect** answers (vertical and backwards) are also high. Students with higher scientific level answer better than non-scientific students. This problem is similar to the problems students usually solve at Physics classroom, so these results are not surprising.

In problem 2 a) the biggest percentage of students **answer Aa2 (vertically)**, an incorrect answer. But by levels, the biggest percentage of correct answers is at Science 3rd level, as in problem 1. Students with less or none scientific background **answer Aa2 (vertically)**, an answer that coincides with the ancient ideas we commented in the HC –these are pre-Galilean students. Most of the students **answer question b) in problem 2 incorrectly** at all levels. That means the scientific background students have is not useful to answer correctly this question.

The third big category is **velocity of the object/ball.** We include below the network of this big category**.** It would seem logical that, if students say that the object/ball will go forward, they must bear in mind that it should be at exactly the same **velocity of the train/lorry**, but it is not true in all the cases. Thus, we introduce a sub-categorization in order to count students that have a good understanding of this problem. (See fig. 2).

Velocity of the ball (V)

- Velocity in the carrier's same direction (V1)
  - The same velocity (V11)
  - Different speed (V12)
  - Not clear - the same speed (V13)
- Velocity not in the carrier's same direction (V2)
  - Opposite direction (V21)
  - No velocity (V22)
  - Not clear (V23)
- Not clear (V3)

Fig. 2: Network of Velocity of the object / ball in problem 1 and problem 2.

The fourth category is the **Type of Justification** students give when answering the problems. According to the general Physics' concept they use to justify their choice, we classify the students' justifications in five big categories that also have some subcategories (See fig. 3).

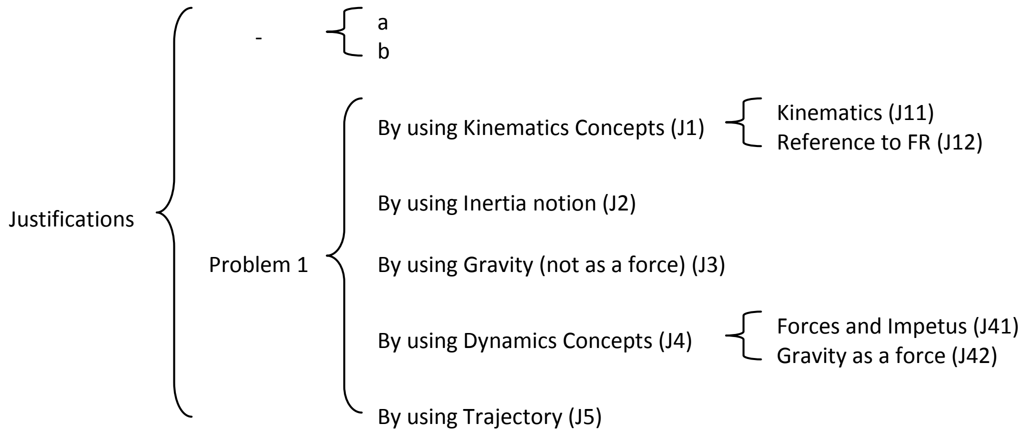


Fig. 3: Network of Types of Justifications answering problem 1 and problem 2.

3. Comparison between problem 1 and problem 2a)

After the analysis of each problem we will compare the students' answers to the two problems. We'll do this comparative study from the categories of the systemic networks.

The first category we compare is **Type of answer** (We won't count here **Not clear** answers).

Table 1: Comparison of types of answers.

Answer to problems 1 and 2a)	Forward	Vertically	Backwards	Not answered
Total problem 1 (122)	41.8 (51)	27.1 (33)	27.0 (33)	4.1 (5)
Total Problem 2a) (115)	33.0 (38)	47.8 (55)	16.5 (19)	2.6 (3)

The results collected in the table indicate that students interpret differently these problems, which are very similar from the Physics point of view.

We also compare the categories of the **velocity of the object/ball when it leaves its carrier in motion**. This comparison says that, mainly, students don't attribute velocity in the direction of the carrier's motion to the object that separates from it, and this category is significantly higher in problem 2 than in problem 1.

To compare the students justifications, we don't consider justification of **Trajectory** because most of these justifications can be considered as a **Kinematics** justification, thus we have a new table of **Reduction of justifications** with only five excluding categories. There are differences in the percentages related to the categories in the two problems. From the differences found in the results of the two problems, we can infer that students interpret each problem in a different way, and they find problem 2 more difficult than problem 1, but in both cases non-scientific students answer both problems worse than scientific ones.

Table 2: Reduction of justifications, excluding categories.

Justification. Summary	**Jd1 Kinematics**	**Jd2 Inertia**	**Jd3 Gravity**	**Jd4 Dynamics**	**Jd6 Not justif.**
Total problem 1 (117)	53 (62)	6 (7)	4.3 (5)	35 (41)	1.7 (2)
Total problem 2a) (112)	40.2 (45)	3.6 (4)	1.8 (2)	13.4 (15)	41.1 (41)

Comments and discussion

The performed research with these specific problems proposed to students has been very useful to evidence that nowadays students participate of many ideas and conceptions identified in pre-Galilean history of science. In particular, many students have a non-relative conception of motion trajectory and velocity; many of them have an absolute conception of these scientific entities.

Students mainly answer problem 1 better than problem 2. This result may be interpreted by the fact that this first problem is more similar to problems that students use to solve in Physics classroom. A very relevant characteristic of these problems is that, while through the question proposed in problem 1 students have to use a FR at rest, in problem 2, that has two questions, students have to use a FR in motion (relative to the observation point) and also a FR at rest.

An interesting comment we can do from these results is that only with question b) in problem 2 have we been able to really know about the students comprehension of the physical situation in which an object drops or is thrown away from a moving system. This interpretation brings us to the importance and relevance of some particular characteristics of problems or questions proposed to students.

Implied from research and comparison with HC, is that the HC would have to be included in the Teacher Training curriculum. Researches done tell us that the topic of Galilean Relativity is not easy, students have to change their own way to see the world in a new way that is against their common way of thinking. This can never be easy, and is more a persuasion issue than a discovering. Thus, teachers will have an essential role in convincing students, and the HC is an important source of new approaches and also of specific ideas for the design of appropriate activities, and also new multimedia resources can be useful; but without an adequate orientation and scaffolding by the teacher, convincing of these new ideas will be quite impossible.

Abstract

A periodic table of elements, following the model of Andreas von Antropoff, was painted in 1934 in a classroom at the University of Barcelona's oldest building. It still has great historical value and has just been recently restored. So, in 2009 it was proposed by the Catalan Board of Chemists, Col·legi Oficial de Químics de Catalunya*, on St Albert's day that secondary school students worked the History of Chemistry preparing and discussing both Andreas von Antropoff's and the 150 years of Mendeleev's periodic table, together with their historical implications. In this study we expose the Catalan Board of Chemists' project disseminating the history of chemistry within Catalonian secondary schools.*

Introduction

Catalonia is one of the 17 Spanish Autonomous Communities with its own independent educational system[1]. So, most of the Spanish and Catalan students from primary and secondary school do not appreciate the impact of science on different aspects of our lives: health, nutrition (Genetic Modified Organisms), new technologies (rockets, computers, nanotechnologies), etc. And they also don't appreciate the impact of the history of science from antiquity to the present day, from the discovery of fire or the heliocentric theory to the laws of relativity. In our context, chemistry students in secondary school cannot appreciate the impact of the history of chemistry from the ancient times with the utilization of metals like copper, iron or gold to the synthesis of drugs or from Democritus' atom proposal to nuclear reactions.

[1] See: www.xtec.cat/estudis/eso/curriculum_eso.htm (Catalan science curricula from compulsory secondary schools, students 12-16 years old) and, www.xtec.cat/estudis/batxillerat/curriculum_bat.htm (Catalan science curricula from secondary schools, students 16-18 years old). [accessed October 29, 2010]

We want to change this adverse situation by the history of chemistry. Usually, the relationship between the history of science and young students is not easy. However, quoting Sir H. Butterfield[2], we cannot increase student's chemistry motivation or a tolerable scientific society without the history of chemistry. We should enhance the incidence of the history of chemistry in classroom. But, how can we do it?

Initially, it is known that there are some young students with not enough interest in science; this is a common problem around the World. What is the reason for this lack of interest in science between teenagers? Nowadays there is more than one reason.

In general, a lack of motivation following several and general studies are presented in our youth; students simply do not have enough motivation for socials, languages, laws, science or in our context for chemistry and its history. In addition, chemistry has a bad image in society; chemistry and science have often been a topic in mass media news, from the printed word to television. However, bad news are more remarkable in media that good news. Unfortunately, secondary school's science students are affected by these circumstances.

To increase students' motivation and make science and its history more enjoyable and understandable, several activities have been suggested correlating theoretical explanations with historical references in the classroom. In this way, many examples could be observed; authors presuppose that readers and science teachers could add several examples:

- Theatre is a good tool used by some teachers to introduce historical science events to students by themselves[3] or by a theatre company[4].
- Cartoons are also used to increase science's motivation in young students. Leopoldo de Meis' books[5] could be used in primary and secondary schools.
- Biographies are also prepared and read in the classroom by teachers and their students. Some examples are Copernicus, Lavoisier, Mendeleev or Watson[6] and others.
- Science museums organize shows about the history of science aimed at young students and general audiences. Only two examples of museums: Oxford Museum of the History of Science[7] with shows like "Observing the Universe", "Penicillin: the Wonder drug" and "From Alchemy to Chemistry". And the Milan Historical Museum[8] that is pleased to offer several Educational Programs with a curriculum in accordance with the Educational Guidelines.
- Finally, radio and digital media could easily be used as a diffusion instrument to give a new and balanced perspective to the history of science[9].

All of these activities are very important to make chemistry and its history understandable for every body, but taking each one of these separated approaches is not enough to stimulate students. If teachers want to have a stronger insight into the relationship between the history of chemistry and young students they will have to apply new educational procedures.

And also Josep M. Fernàndez-Novell & Carme Zaragoza (2010) Broadcasting Science: a new bridge between science and society. M. Kalogiannakis, D. Stavrou & P. Michaelidis (Eds.). pp. 57-62.

When science teachers talk about science and its history in the classroom usually they focus mostly in its past, but too many students feel these things are not linked with them and not linked with the present day. For example, the discovery of the DNA structure (middle 20th century, 1953) or when the first humans walked on the Moon on 21st July 1969. These events feel like a long time ago for students although they happened when their parents probably were still children. It is very difficult for students understand these contexts because they are unable to put themselves in the past and think about these situations.

Furthermore, if teachers want to motivate secondary school students into enjoying science and its history they need to find some science activities which take place closer to the student's surroundings.

In this way, to increase student's understanding and motivation towards chemistry we need to find links between the history of chemistry and the present day. Some of these links are related with:

a) Science and street names.
Teachers could prepare exercises for students to find near to their homes, in Barcelona and other cities, many street names that are related to famous chemists and scientists, for example Marti i Franquès street surrounding the Faculty of Chemistry, the Puigvert gardens, the silver jewellers' street, etc.

b) Science Nobel Prize winners that visited the city.
Another interesting thing that teachers could do is to explain and organize different activities about the times when some of the most important scientists visited the students' cities. Catalan science teachers could prepare several works on Sir Alexander Fleming, Albert Einstein or other Nobel Prize winners when they came to Barcelona or came to their place. Working on this, students could obtain pictures from internet or local newspapers to recall that past meetings and put themselves in those times.

c) Promoting science conferences.
In this way it could be interesting that secondary school students could work on Sir Harold Kroto or/and on professor Josep Font conferences[10]. In the event organized by the Faculty of Chemistry from the University of Barcelona, as part of the International Year of Chemistry, Sir Harold Kroto, winner of the Nobel Prize in chemistry 1996, has been invited to give the talk "Carbon in nano and outer space" about fullerenes or buckyballs (they resemble balls used in soccer). Furthermore, several lectures delivered by chemists were organized by the Autonomous University of Barcelona, as part of the International Year of Chemistry in which secondary school science teachers were invited to participate with the aim of bringing chemistry closer to everyone. The first conference was "Molecules combating diseases and restoring health" by professor Josep Font, and it was about the history of medicines like quinine, aspirin, penicillin or AZT.

All these links could become an important tool to teach the History of Chemistry in primary and secondary levels and to motivate young students. We present in this article a collaboration between the Catalan Board of Chemists (CBC)[11] and the University of Barcelona for spreading chemistry and the History of chemistry to Catalan science secondary school students.

What is the project?

Our aim is to put emphasis on chemistry and history of chemistry understanding in secondary school classrooms. With this in mind, on Saint Albert's day 2009[12], the Technical Section of Education from the CBC in collaboration with the Faculty of Chemistry from the University of Barcelona prepared some activities directed to secondary school students about the classification of elements that link the history of chemistry to the present day.

To relate to the history of chemistry, it is necessary that we go back to 1934, to classroom 111 in the historical building of the University of Barcelona. In this classroom, after a proposal by professor García Banús, a periodic table was painted on one of the walls. This periodic table had the same structure, symbols and colours than the periodic table from Andreas von Antropoff[13].

---

[10] The Nobel Prize in Chemistry 1996 was awarded jointly to Robert F. Curl Jr., Sir Harold W. Kroto and Richard E. Smalley *"for their discovery of fullerenes"* and professor Josep Font i Cierco, chemistry from the Autonomous University of Barcelona. http://www.uab.es [accessed February 27, 2011]

[12] Saint Albertus Magnus or Doctor universalis was declared in 1941 by Papal decree the Saint Patron of all who cultivate the natural sciences. In Spain Saint Albert's day is the 15th November.

[13] On this point see Eric R. Scerri, (2007) The periodic table: its Story and its Signifiance. Oxford University Press, Oxford; Eric R.Scerri (2009) *Selected papers on The Periodic Table*. E. Scerri Ed. University of California, Los Angeles, USA. And also, Claudi Mans (2009)

In addition, at that time in this classroom, professor García Banús put up a lecture hall with a big laboratory table with water facilities to be able to set up and present chemical experiments in front of the students. This allowed chemistry teachers to have a lecture and also to perform experiments while giving theory explanation. It was the first lecture hall used as a laboratory classroom in the University of Barcelona.

As time passed and the painted periodic table colours were fading, a restoration was needed. When we moved forward to the 21st century, the University of Barcelona decided to restore von Antropoff's periodic table. On 3rd April 2009 this renovated periodic table was shown again to the university members and general public[14].

This important restoration was combined with the celebration of the 150th anniversary of the first presentation in society of the "periodic table of the chemical elements" by Dmitri Ivanovich Mendeleev in 1859, one of the most important episodes in the history of chemistry[15].

These two events gave CBC in collaboration with the University of Barcelona the opportunity to prepare some activities around Saint Albert's day to involve secondary school students, chemistry and its history. These activities tried to engage the majority of secondary school chemistry teachers so that they could motivate more and more secondary school students.

The history of chemistry can raise new options to secondary school science teachers to increase science knowledge to many secondary school students. It is necessary to continue building bridges between chemistry and its history or between science and its history[16]. With this approach, we get more teachers involved with the history of chemistry explanations.

Methodology

The CBC and the University of Barcelona sent a letter, addressed to the chemistry teaching staff of secondary schools, proposing two different activities to commemorate Saint Albert's day.

First activity

The first activity was developed in science classrooms. Students had to work on the periodic table of the chemical elements and its history starting before Mendeleev's periodic table (an organization of macroscopic chemical properties of the chemical elements according to their atomic weight), continuing with Andreas von Antropoff's periodic table (an organization of the chemical elements according to their atomic number) and finishing with the standard periodic table that present day students use (chemical properties are an approximate manifestation of the electronic configurations of the atoms of the elements). For a review see Eric R. Scerri 2009, footnote number 13.

Teachers and students could work on the general vision of the periodic table of elements from the Zaragoza & Fernández-Novell's text[17], that was sent in pdf format to secondary school science teachers. In this article Mendeleev's periodic table was used to teach chemistry and to discuss the properties of the elements predicted before they were discovered. The study of Andreas von Antropoff's periodic table was supported by a Claudi Mans' article[18] in the magazine *Notícies Per a Químics,* News for Chemists, edited by the CBC. In this article, which was also sent to all secondary school chemistry teachers, the history of the periodic table painted in the University of Barcelona, its restoration and the recent history of chemistry from the University of Barcelona was exposed.

[18] See footnote number 13.

Second activity

The second activity took place in classroom 111 of the historical building of the University of Barcelona, where the restored periodic table and its history was showed, presented and explained to everybody. This presentation was performed in front of secondary school chemistry teachers, theirs pupils and the general public who attended the session.

Results

Participation

All data in the table were obtained from the information that the secondary school teaching staff had sent to the organizers.

The welcome and participation of schools in these activities were important. As it can be observed in this table, the participation was of more than 1500 students, boys and girls, between 15 and 18 years old. Doubtlessly, they transmitted their motivations and interests in chemistry and its history to their parents and friends.

Table 1. Results 2009

Participating Schools	54
Secondary School Students	547
High School Students	971
Total.	**1518**

The second activity took place in classroom 111 of the historical building of the University of Barcelona, and it was related to the presentation of recent history of chemistry to students and general public. The considerable participation of secondary school science teachers and students in this event showed the importance of linking the evolution of chemistry in the city of Barcelona, the University of Barcelona and secondary school students from Barcelona.

Working questions

Several examples of questions posed and worked in classroom by secondary school chemistry teachers are presented:

- How can you explain the differences between von Antropoff's and Mendeleev's periodic tables? Remember that in Mendeleev's times chemists didn't know about the atoms electronic configuration (teacher's suggestion).
- Who were Newlands, Döbereiner and Meyer?
- Could you write a little story about the classification of elements?
- Could you write a little story about the discovery of elements?
- How was chemical knowledge passed on from generation to generation?
- Controversies between the ancient idea of element and 19th century element classification.
- Which concepts guided chemical investigations?
- Which were the last elements found by Seaborg?

Each teacher worked on these activities in the best way for their students. So, as well as Mendeleev and von Antropoff's periodic tables, pupils worked on Döbereiner's "triads", Newlands' "octaves law" and Meyer's "elements classified by valence". They have to answer some questions about the history of the atom, the elements and the periodic table. These questions are related to the students' level: last years of compulsory secondary school students (15-16 years old) and non-compulsory secondary school students (17-18 years old).

It is important to realize that students' works, their classroom discussions about the historical discovery of the elements and their classification related to von Andropoff's periodic table were very successful (teacher's information).

Working the differences

Secondary school students found few differences between Mendeleev's and von Antropoff's periodic table of elements, summarized as:

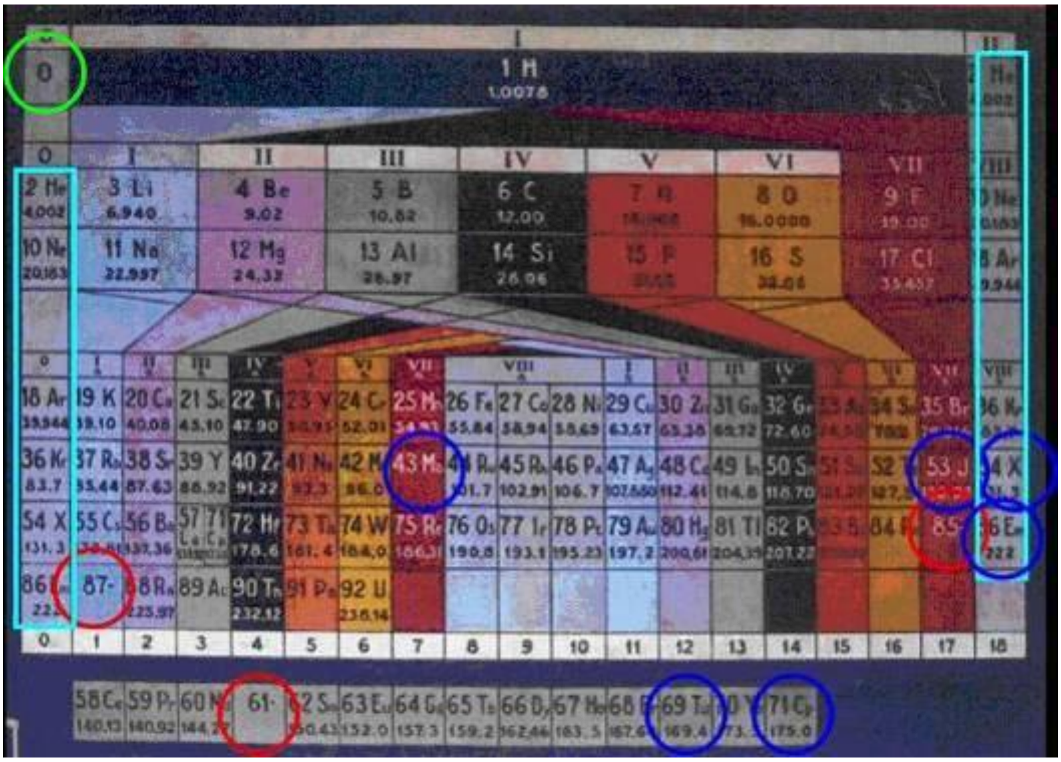
Mendeleev's periodic table was proposed supposing the property of atomic weight constant for each element, and Mendeleev's historical support was based on the fact that his predictions were successful. However, in the early twentieth century the property of atomic number was chosen as more appropriate.

The view that the periodic table should be thought of primarily as an organization of macroscopic chemical properties of the elements, rather than as a tool for accessing the electronic structure of the atoms of elements, is important to present the history of the periodic table to young pupils. Secondary school students must be taught that the elements classification was prepared when chemists didn't know about the electronic configuration of the atoms of elements.

Secondary school students found many differences between von Antropoff's periodic table, represented in the figure below, and the current periodic table that appears in their secondary school textbooks.

Surprisingly for secondary school students, von Antropoff's periodic table has an element with number 0, that is no protons and no electrons but only neutrons. It was a hypothetical element predicted by von Antropoff that doesn't exist. At this point students and teachers could discuss the importance of mistakes and controversies in chemistry evolution, because the advance of science involves not only established conclusions, but also strong controversies. Even mistakes could be helpful in chemistry education.

The group of noble gases has doubled; there is one column in each side of the periodic table.



The restored von Andropoff's periodic table at the University of Barcelona, with the points that need an explanation.

In this periodic table appeared three empty places: numbers 61, 85 and 87. These three elements were not discovered by 1934. These elements are: 61 Promethium (Pm), 85 Astatine (At) and 87 Francium (Fr). Students easily understand that the number of the discovered elements is period-depending and, for this, the discovery of elements is increasing with time up to the present day.

There have been many changes in the elements symbols from von Antropoff's periodic table to now:

- Number 43 before 1934 was thought to be the element Masurium, represented as Ma, but was synthesized in 1937 as the Technetium element, represented as Tc.

- Number 53 Iodine was represented as J because its name in old German language is Jod, now represented as I.
- Number 54 Xenon was represented as X, now as Xe.
- Number 69 Thulium was represented as Tu, now as Tm.
- Number 71 was thought until 1950 to be the element Cassiopeium, represented as Cp, but now it is named as Lutetium, Lu.
- Number 86 was named Radium Emanation from 1910 to 1960 and was represented as Em, now it is the element Radon, Rn.

Clarifying these differences increased students' interest in chemistry and its history, they were asking for an explanation that they put in context with the history.

Conclusions

- Collaboration between the CBC and the University of Barcelona allows the dissemination of the history of chemistry within Catalonian secondary schools.
- Finding links between the history of chemistry, the history of science and the present day is a prerequisite to involve young students in this venture.
- Working with a restored painted periodic table and the 150th anniversary commemoration of the social presentation of Mendeleev's periodic table was a good help for science teachers to spread the history of chemistry.
- This project allowed us to involve more teachers, more secondary schools, more classrooms and more secondary school students in disseminating the history of chemistry. A lot of secondary school chemistry teachers presented the history of chemistry in their chemistry courses.
- As Kuhn proposed, the history of chemistry produces a crucial transformation in the image of chemistry in young students. The majority of secondary school students that had participated in these activities got a better and more positive image of chemistry and the history of chemistry; they could spread this image to their family and friends.

THE ORIGINS OF TECHNICAL EDUCATION IN INDIA: STUDY OF DIFFERENT APPROACHES

Samir Kumar SAHA
Mechanical Engineering Department, Jadavpur University, Kolkata, INDIA
sahasamir7@yahoo.com

Abstract

The present paper is a study of the different growth models of evolution of Technical Education in India. Initially it was the colonial model, in which engineering colleges were established mainly in five places in India. The colleges in Roorkee, Poona, Calcutta, Madras and Bombay were utilized to produce 'technical hands' for the empire. However, in the early twentieth century, three nationalistic models developed. In Calcutta, it was the National Council of Education, which, in defiance of the University Act of Curzon wanted to establish National Colleges and National Schools. Only the College of Engineering and Technology developed out of this model and became the Jadavpur University. In Banaras, Malaviya started the Banaras Hindu University, where Technical Education, Law and Medicine were imparted together with the inculcation with the spirit of Hindu religion 'for moral growth'. However, J. N. Tata, after negotiation and fighting, could establish the Indian Institute of Science (IISc) as a premier research institute in India. It was also a teaching institution, different than the Indian Association for the Cultivation of Science (IACS) established in Calcutta by Sir M. L. Sircar in 1876. This grew into a reputed school in India, with active collaboration of the British as well as National Industrialists –a major prerequisite for industrial and economic growth. There were other small attempts.
The Universities were mainly imparting arts and science education in India from 1857 and were affiliating bodies. Thus, Technical Education started in India in the 1860s, almost at the same time at UK, but the visions were different, sometimes conflicting.
It was only in 1951, the IITs (Indian Institutes of Technology) were established based on the Sarkar Commission Report in 1946. The paper concludes by tracing their growth as ranked institutes in world educational systems ranking.

Introduction

The history of Technical Education and its inter-relationship to development of technology, industry and economy is an important field of study. Few works have been done on the Indian scenario keeping this inter-relationship in view. A study of the development of Technical Education in India reveals the Technical Education in British India was not established with a view to build-up a technological reliant India.

A deeper study of growth of Technical Education in India took us to different roots: the colonial model, the nationalistic model, the research model etc. the present study tries to highlight the nature of the different models in technical education perspective framed in a historical background for India.

Colonial Models of Technical Education

1. Guindy Civil Engineering College, Chennai

The first survey school was founded at Guindy, Madras in 1794 by Michael Topping, the East India Company's astronomer, and geographical and marine surveyor at the Presidency of Fort St. George, to do the necessary survey works and to assist British surveyors because land use in India was of precedence. The survey school started training Subordinate Engineers, Upper Subordinates, Lower Subordinates and Overseers, giving them elementary knowledge of Civil Engineering. [6]

By 1842, it was realized that the survey school was inadequate for the needs of the Public Works Department, and the establishment of an engineering college was desirable.[11] An industrial school, attached to the Gun Carriage Factory, was established in 1842 in Madras, which amalgamated with the survey school in 1858 and was redesignated as Civil Engineering School. In 1859, the name of the institution was changed from 'Civil Engineering School' to 'Civil Engineering College'.

The subjects taught were Surveying, Plotting, Planning and Estimation, Mechanical Engineering, Hydraulics and Elementary Mathematics etc. The first department was created in 1862 to train Commissioned Officers and Civilians as Assistant Engineers. In 1886 the Civil Engineering College came to be known as the College of Engineering. [6]

2. Thomason Civil Engineering College, Roorkee

The first engineering college in colonial India, Thomason Civil Engineering College was established in 1847 at Roorkee for training of civil engineers for the PWD works with the initiative of James Thomason, the Lieutenant Governor of the North Western Provinces. The college provided education to a limited number of students under the overseer and subordinate categories. Thomason chose the location at Roorkee, near the Solani Aqueduct on the Ganga Canal, because large workshops there would provide facilities for instructing civil engineers. [8] The college started functioning on January 1, 1848. Later, the college was named after James Thomason as 'Thomason College of Civil Engineering' in 1854. Initially, only Civil Engineering was taught in the College, but after that Electrical, Mechanical, Textile Engineering etc. were incorporated in the curriculum. The Roorkee College became a model and catalyst for the other engineering colleges in India.

3. Calcutta Civil Engineering College

Being impressed by the success of Roorkee College, Lord Dalhousie granted the starting of engineering colleges in each of the presidencies. In Bengal, A College of Engineering was started by the name of 'Calcutta Civil Engineering College' on 24th November, 1856, in the premises of the Writers Building, Calcutta. The objectives of the college were the same as those of Roorkee College; to train candidates for different levels of employment for the public works and revenue departments. Hence there were courses for overseers and sub-overseers also. [7]

In 1865, the college merged with Presidency College, Calcutta and from 1865 to 1869 the college functioned as the Civil Engineering Department of Presidency College. In 1880 the engineering department was given back its separate identity as a college by transferring it to the buildings of the old Bishop's College at Shibpur in Howrah, so that both civil and mechanical engineering students would be able to receive theoretical training in the PWD workshops in Howrah. The college was named as 'Government College, Howrah'. It started imparting training in Civil as well as Mechanical Engineering. In 1921, the name of the college was changed to 'Bengal Engineering College'. The college had mechanical courses at the engineering and apprenticeship level from the very beginning.

4. Poona Engineering College

Bombay and Poona had a concentration of industries and another engineering college was established in Poona in 1856. Initially, the Poona Engineering College was started as the 'Poona Engineering Class and Mechanical School' to train subordinate officers for carrying out public works like making of buildings, dams, canals, railways and bridges. [9]

The courses in this college were more diversified and emphasised several more scientific disciplines than what was imparted at the other similar engineering colleges. Two new classes, an Agricultural class and a Forest class, were added to the college, and the name of the college was changed from 'The Poona Civil Engineering College' to 'The College of Science'. The objective was to open general science courses leading to B.Sc. degree of Bombay University.

In 1911 all non-Engineering courses closed, and the college renamed as 'College of Engineering, Poona' (COEP) and the name continues today. From then on, the college has gone on expanding adding new departments and new wings by the year. B.E. (Mechanical Engineering) course was introduced in 1914. An important feature of the college was its well equipped workshops where practical instructions were conveyed and at the same time various types of work were executed on orders from the government and the public. [1]

5. Victoria Jubilee Technical Institution

During the Golden Jubilee celebration of Queen Victoria's reign, Victoria Jubilee Technical Institution (VJTI) was founded in Bombay, in 1887 by private efforts to provide courses of instruction suited to the requirements of the skilled manpower for growing Bombay Textile Mill industries. Institute started with only two departments, namely,

- the Sir J.J. School for Mechanical Engineering and
- the Ripon Textile School

It continued with the diploma courses until 1944 when it expanded its scope to degree courses in Electrical Engineering, Mechanical Engineering and Textile Technology. This was the only institution in India at that time with largest number of machines and apparatus. And this feature attracted more students from the Punjab, Assam, Madras, Sind, the Central Provinces and from many other places of India. The great names associated with this institute included Dadabhai Naoroji, Pherozshah Mehta, Dinshaw Wacha, R.D.Ranade and philanthropic members of Petit, Jeejabhai and Wadia families. Some of the first teachers of the National College of NCE, Bengal were from VJTI. The institute was renamed as 'Veermata Jijabai Technological Institute' on January 26, 1997.

In England civil, mechanical, electrical and applied chemistry co-existed side by side. But until the 1920s only civil Engineering could be studied to degree level in the Engineering colleges in India. The curriculum and the training in Roorkee, Guindy, Poona and Shibpur were based mainly upon PWD, Railways and other Government requirements of only subordinate grades of employment, particularly in government services. [10] Civil Engineering remained the favoured subject. The colleges opened during the nineteenth century in India were mostly called 'civil engineering colleges', while the other branches – e.g., electrical, mechanical and mining engineering – remained neglected and repeated attempts to develop electrical and mechanical engineering degrees at Calcutta, Poona and Madras failed in the early years. [10] VJTI was an exception perhaps for the industrial and textile bases in Bombay.

The Nationalistic Models of Technical Education

1. Dawn Society to National Council of Education, Bengal to College of Engineering and Technology to Jadavpur University

The colonial model of technical education with the establishment of Guindy College, Thomason College, Calcutta Civil Engineering College, Poona Engineering College and Victoria Jubilee Technical Institution travelled in one direction. Parallelly, a national model was also attempted to be developed in Calcutta, at the National Council of Education, Bengal (1905-1906).

Generally speaking there were no institutions in India where higher technical instruction on modern lines as compared to Germany or U.K. could be imparted. "*Government was interested in only in technical and industrial schools, not in higher forms of scientific and technical education*". [1] To quote Satpal Sangwan "*The real fault in the British education policy was, the undue and disproportionate attention devoted to literature, as compared with physical sciences and the cognate branches of practical instruction*". [2] As a result, the scientific and practical educations were neglected. Students had to go abroad to get the requisite training. But only a limited number could avail of this opportunity. It was felt by a section of nationalists that scientific and technical education was a necessary precondition to economic and industrial growth of India, to put it at par with other industrially developed countries, particularly for an India, free from the shackles of foreign rule.

The Dawn Society established in 1902, by Sri Satish Chandra Mukherjee had been functioning as an association for the promotion of moral training and general culture as well as business and commercial habits among young men under the inspiration and guidance of the founder. On Nov 4, 1905, in a meeting, the Dawn Society encouraged the audience to go in for the establishment of a national university. Based on the ideas of Dawn Society, in 1906, a group of Bengali intellectuals and the leaders of the Swadeshi Movement decided to set up a truly National College that would challenge British rule by offering alternative education to the masses *"on national lines and under national control*". [12] Thus the National Council of Education, Bengal was founded on 11th March, 1906 without Government support and financial help. Its main aim was to provide education –literary, scientific and technical on national perspective i.e. a blend of the best of the east and the west. The Bengal National College and School, the model institution was established by the Council in August, 1906. Right from the beginning, the Bengal National College developed a model of 'three dimensional' system of education combining teaching with factory work. Initially, the institution had four departments –Literary, Scientific, Technical and Commercial.

Some of the leaders of the council started feeling that the extreme nationalist flavour became more a hindrance than a help to the academic progress of the college, and the economic problems of the country could be solved by the promotion of technical education alone. On June 1, 1906, Sri Taraknath Palit (breaking away from NCE) established a second organisation, rival to the National Council of Education, named 'Society for Promotion of Technical Education' (SPTE) and later founded the Bengal Technical Institute (BTI). This was the first nationalist technical school in India. *"They took their ideal of technical education from the systems that prevail and have succeeded so well in Europe and America and it was thought advisable that so far as it lay in their power their systems should be shaped on those models"*. [4]

In BTI, two courses were offered: primary courses which include practical training in Mechanical fitting, Electrical fitting, Carpentry, Drawing and Surveying. And the secondary courses included Mechanical Engineering, Electrical Engineering, Dyeing and Bleaching, Industrial Chemistry and Economic Geology and Mineralogy. BTI also had a manufacturing department. NCE and SPTE formed a combined institution in 1910. Later the institution was shifted to Jadavpur in 1924 and was renamed as the 'College of Engineering and Technology' (CET) in 1929. [13] The CET adopted the aims, ideas, academic and administrative policies of the BTI. [4] The National Council of Education, Bengal which was established in 1906 to provide education on national perspective had initially two technical courses in the National College – Mechanical and Electrical along with other subsidiary technical subjects. In 1921 it started the first Chemical Engineering Department in India. In 1956 the College of Engineering and Technology became the Jadavpur University and successfully established itself as one of the best scientific and technological institutions of India, with a strong engineering faculty and with Science and Arts faculties also.

The growth of this model, carried on by extremist Swadeshis was done without any Government help in the initial stages. However, the quality of education got recognised all over world.

2. Malaviya's Banaras Hindu University: Hindu Model

Another nationalistic model was initiated by Pandit Madan Mohan Malaviya with the establishment of the Banaras Hindu University with different objectives. According to him the two foremost priorities of the country were the freedom of the country and nation building. The priority of nation building could be achieved only through the rapid industrial and agricultural development and for this a greater facilities for technical and industrial education would be required. [14] One of the objectives was to make provision for imparting instruction and technical training in the different branches of engineering. Hence, in order to meet the future immense needs of the 'Resurgent Modern India', he visualized a 'Modern University' that combines the best of Indian education with the best tradition of modern universities of the west. The aim of the University, by Malaviya's vision, were to promote Hindu Shastras and Sanskrit for preserving and popularizing the best thought and culture of Hindus as well as to advance scientific and professional knowledge. [14]

Malaviya first propounded the idea of a Hindu university in 1904 at a meeting in Banaras, presided over by the Maharaja of Banaras who had been his co-worker in the founding of the University. It then took ten years for Malaviya to find a site and to raise the necessary funds with the help of Zamindars and Rajas. Malaviya, Follower of 'Hind-Hindi-Hindu' model, had already annexed to his brand of politics the emotional forces of Hindi and Hindu revivalism. [20]

The Banaras Hindu University Society was registered in July 1911 and the Benares Hindu University Act was passed in 1915. The foundation stone was laid in 1916. The already existing Central Hindu College, founded in 1898 by Mrs. Annie Besant, founder of the Theosophical Society and British reformer, served as a nucleus for this institution.

To explore the possibilities of industrial development in India, in 1916, the government of India appointed an Industrial Commission under the Chairmanship of Sir Thomas Holland. Malviya was one of the Indian members of the commission and gave a 'Note of Dissent' [5] which illustrated the industrial and economic problems of then India and an indictment of the British economic policy towards the country. [15] Malviya wrote "*in the present economic condition of India there is no branch of education for which there is greater need than scientific and technical instruction*". The most intriguing fact is that, he did not mention anything about the NCE model of national education, particularly technical in his note, while he had some connections with Sir Rashbehari Ghosh etc. However, he gave a proposal for the establishment of an Imperial Polytechnic. [15] Probably, he was not much enamoured with the ideas and achievements of Bengal renaissance men and he wanted to chart his own path, which was quite natural in the then condition of Indian struggle for freedom.

Education in Engineering and Technology commenced at the BHU with the establishment of the College of Engineering in 1919 with two departments, Mechanical Engineering and Electrical Engineering. Later a department of Mining and Metallurgy was added to the college and later it became a separate institution as College of Mining and Metallurgy (MINMET) in 1923. This was more in continuation with India's early achievements. Another college named 'College of Technology' (TECHNO) came up in 1938. In 1968, these three premier engineering Institutions had been amalgamated to form the Institute of Technology (IT-BHU). The first-ever combined Degree Courses in Mechanical and Electrical Engineering, as well as Mining Engineering, Metallurgical Engineering, Ceramic Engineering and Pharmaceutics in India were initiated at BHU. Pandit Madan Mohan Malaviya was greatly interested in industrial and technical development of the country and he had been making all efforts to promote technical education. [14] He combined his roles of politician, administrator and educator well by remaining the Vice Chancellor of BHU from 1919 to 1939.

3. Indian Institute of Science: Research Model

Apart from the swadeshis, there were some individuals and industrialists, and through their efforts and financial help Technical Education did make immense headway in India. The first research institution was started in Calcutta in 1876, the

Indian Association for the Cultivation of Science, by Dr. Mahendralal Sarkar. Its primary purpose was to foster high quality fundamental research in frontier disciplines of the basic sciences. But it did not have any programme for Technical Education.

In the western part of India, Mr. Jamshedji Nusserwanji Tata, one of the leading industrialists of the colonial India, realised the importance of scientific and technical education and research and this led him to conceive of an institution of higher learning which would pay greater attention to science and would train the bright young students after they left the universities. He symbolized the rising aspirations of the Indian bourgeoisie which were becoming conscious of the technological (societal) applications of scientific research. Mr. Tata's main aim was to build up a world class institution with well established link with Industry that will furnish a thorough post graduate courses of studies and supply one of the major needs of the country; scientific researchers and technocrat leaders. He took John Hopkins University of Baltimore, the first Post Graduate institution in the world, as a model for his institution. [16]

On 31st December, 1898, the provisional committee including J.N.Tata and Padshah met Lord Curzon, the newly appointed Viceroy with their proposal to build an institution. But, Lord Curzon, because of his anti Indian bias became the villain again. He tried to ruin Tata's plan for an Indian University of research, because he did not favour spreading higher level technical education in India. [11] He expressed his doubts about the scheme. Ultimately, the Government suggested that the scheme (the location, expenditure) for the institution be critically evaluated by one or two outside experts. The provisional committee on the advice of Padshah suggested the name of Prof. William Ramsay, who was one of the first British scientists to win Nobel Prize in 1904. Prof. William Ramsay toured India, visited several educational centres, and submitted a fairly detailed report on the academic, administrative and financial structure of the institution. On the academic side, he was clearly in favour of science and technology. Sir William Ramsay prunes Tata's scheme from a University to an Institute. [16]

The immense effort of Burjorji J. Padshah ultimately led to the establishment of the Indian Institute of Science in 1909 at Bangalore, as a research organization devoted mainly to experimental sciences. Best brains from the country, abroad and industry were pulled together. With Ramsay's recommendations the institute got its first director Morris Travers in 1909. Under the guidance of some very able Indian directors like C.V.Raman, J.C.Ghosh and Satish Dhawan the institute flourished as a premier post graduate research organisation and a rich source of talented scientific manpower in India.

4. Other Small Societies

In the mid-nineteenth century, there were also some individual and group efforts to popularize the modern western science through the medium of vernacular. The most important effort was the establishment of Aligarh Scientific Society in 1864 by Sir Syed Ahmed Khan.

"The Muslims in India were as alienated from western education as were the Hindus. Both colonial and structural factors were responsible", to quote Zaheer Baber. [5] Sir Syed Ahmed Khan tried to represent the Muslim viewpoint and initiated an educational project. One of the endeavors of this society was to translate English books in vernacular to percolate science and technology to masses. He established the Mohammedan Anglo Oriental College in 1877 in Aligarh and patterned the college after Oxford and Cambridge Universities. Finally this college rose to become the Aligarh Muslim University in 1920. Aligarh got a quite unusual amount of British patronage including a personal donation from the Viceroy, Lord Northbrooke.

On the same line Bihar scientific society was established in 1868 to publish scientific books in Urdu. Similarly, another society was formed by a group of teachers associated with the Delhi College. These societies played an active role in teaching and translating western scientific books into Urdu. However, they remained only fringe efforts.

University Model: the unfinished tasks

The foundation of Universities was another development under the British rule. Sir Charles Wood's Education Dispatch of 1854 can be regarded as the forerunner of modern university education in India. In 1857, three universities were established in the three provinces of Calcutta, Bombay and Madras. [17] The expansion of the University system was slow. In the first decade of the 2oth Century, there were only five Universities. All of them were modelled on the University of London and all of them were affiliating and examining universities, not teaching universities. Postgraduate work was confined to the colleges which were not properly equipped for such work and so the quality of postgraduate work was not of a very high order. The University curricula were inadequate to meet the needs of a scientific and industrial age. Thus the universities in its early stage, failed to contribute much to the advancement of knowledge in India, which was surely one of their main functions. When the Bombay University was established, it had no faculty of science and the only course in engineering was in Civil Engineering. Kolkata grew with a strong science base. Under the guidance of Sir Ashutosh Mukherjee, the Calcutta University produced the torchbearers of renaissance in Indian science like Acharya Prafulla Chandra Ray, Acharya Jagadish Chandra Bose and their students Prof. Satyendra Nath Bose and Prof. Meghnad Saha. [17] The University College of Science and Technology was established in 1912 in Kolkata, and many eminent scientists were associated with this institution. However, the progress of technical education was hampered due to the lack of Government support and funds as also an alienation of the University model from that of Germany in particular.

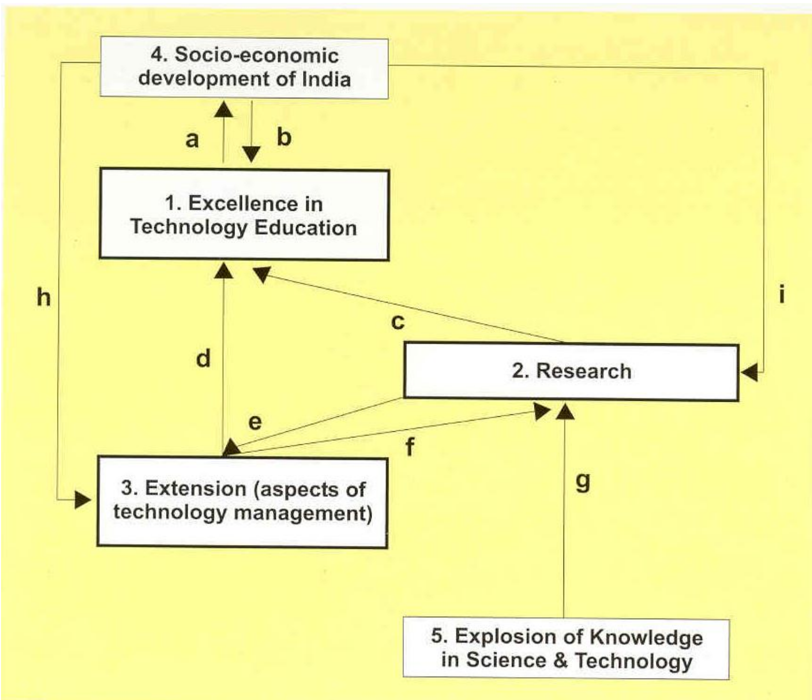
Although the universities offered a programme of undergraduate studies in pure and applied sciences, enrolment in these courses throughout the nineteenth century was very low, because, opportunities for Indians to advance in the scientific services were limited by colonial rulers. Most students preferred arts courses or professional courses like law or medicine. This naturally hampered the growth of higher scientific and technical education within the domain of the university system.

Some universities became predominantly technical but not technical institutions up to the 1960s, until the Kothari commission report came out. [21]

Indian Institute of Technology (IIT): PG and research model

During the Second World War period (1939-1945), the Government of India began to realise the importance of organising Technical Education in the country on systematic lines. The first major step in that direction was taken in 1945 when the Government of India on the initiative of Sri Ardeshir Dalal, a visionary director, Tata Iron and Steel Company, appointed a Committee of industrialists and educationists, under the chairmanship of Sri Nalini Ranjan Sarkar, to survey the entire question of Technical Education in India and to make definite and concrete recommendations in this respect. [18] Until the establishment of the Sarkar Commission in 1946 (the report was published in 1949) –there was no specific thrust towards higher technical education and research in India. In their interim Report in 1946, the Sarkar Committee recommended that four Higher Technical Institutions should be set up as soon as possible, one each in the east, west, north and south. [18] Establishment of the Indian Institute of Technology Kharagpur in 1951 started the realisation of this plan.

The five core elements of the IIT vision, first articulated by the Sarkar Committee, and their relationships as given in the following diagram, suggests that the priority of the IIT system was clearly on education, followed by research and extension. [19]



The IITs were created with foreign technical collaboration, UNDP assistance and modelled on the Massachusetts Institute of Technology and the University of Manchester pattern and to train scientists and engineers with the aim of developing a skilled workforce to support the economic and social development of India after independence in 1947. [18] The first IIT was established in 1951 in Kharagpur in the state of West Bengal with Sir J. C. Ghosh as the Director. The other 3 IITs came into existence in a short span of a decade in Bombay, Madras and Kanpur. The College of Engineering, Delhi and the Roorkee University were converted to IIT in 1961 and 2001 respectively and a new IIT was set up in Guwahati in 1994. Now, IITs are a group of fifteen autonomous premier engineering and technology-oriented institutes of higher education established and declared as *Institutes of National Importance* by the Parliament of India [IIT Act, 1961].

To review the work and progress of the IITs, the India Government had appointed the Nayadumma Committee in 1984 and Ramarao Committee in 2004. The Ramarao committee had highlighted several of the issues involved and made recommendations regarding governance, faculty matters, research enhancement, entrance exam, linkage with industry and funding policy etc. For recruiting new faculty members, the IISc practices were considered more flexible system than the IITs. The committee made a comparison of the IITs and IISc practices in this regard and recommended that IISc system may be adopted by the IITs for the faculty induction, assessment and promotion. [19]

The IITs have earned worldwide fame due to sincere efforts of faculty, students and administration. The IIT system is one of the major success stories of independent India and ranked amongst the topmost institutions in the world in all ranking systems. The autonomy and academic ambience created in these campuses have attracted best faculty and students all over the world. But how far the IITs succeeded in conducting research and development at internationally competitive levels and succeeded in producing engineers 'on par with the best in the world?' –are the most frequently raised questions and is subject to further study, as India still remains a low ranked country in terms of technological education and research.

Conclusion

India's growth is very nonlinear. The evolution of Technical Education is one area which shows the same characteristics.

Predominantly an agricultural country, India had a weak Industrial System compared to European Countries and America. Under the British rule, Technical Education developed in India 'by the colonials, for the colonials and of the colonials'. Resurgence of nationalism encouraged leaders to go for independent national models of Technical Education. Of these the National Council of Education, Bengal was developed by the moderate Swadeshis, but developed into a good research institute (Jadavpur University) only in the 21st century. However, the IISc model and the IITs, which were developed with the assistance of technically developed countries, one at the beginning and others during the middle of the 20th century, took quickly their position in the international rankings of higher education in the world.

This indicates, though technology was very country specific, a global connection together with nationalism helped in development of better models for Technical Education.

EARLY SCIENTIFIC INSTRUMENTS FOR TEACHING PHYSICS IN THE UNIVERSITY OF BARCELONA

Santiago VALLMITJANA RICO
Departament de Física Aplicada i Òptica, Universitat de Barcelona, SPAIN
santi.vallmitjana@ub.edu

Abstract

Although the University of Barcelona was founded in 1450, there is no evidence of the existence of scientific instruments for teaching until the 19th century. According to our archives, in the middle of this century it is on record that classes of Physics, Astronomy and Experimental Physics among others were taking place in the University of Barcelona.
For this reason, at that time the University acquired the first instruments for the teaching of Physics, following the recommendations made by the educational ministry, which increased notably in number until the end of the century and have continued to do so since then. Now the collection consists of about 250 instruments belonging to the sections of Kinematics, Mechanics, Statics, Dynamics, Hydrostatics, Acoustics, Optics, Static-Electricity, Electricity and Magnetism.
*This study analyses the existing scientific instruments acquired in the 19th century and correlates them with a handwritten list dated 1868 found in our archives. Then a further cross-correlation is carried out with the official lists that appeared as a consequence of the educational reforms promoted by the Directorate General of Public Instruction (*Dirección General de Instrucción Pública*).*

Introduction. The political background in Catalonia in the 18th and 19th centuries

In order to understand how the centres of science culture evolved, it is important to know the framework of Catalan society in the 18th century. At the beginning of this century student disturbances were very frequent, especially pro-autonomy movements in Catalonia. In response to all these facts, in 1714 king Philip V forced the University to move from Barcelona to Cervera [1]. This town is located in western Catalonia, about one hundred kilometres away from Barcelona. As a reaction against the imposition from Madrid and also for convenience reasons, several schools with university-like education were created throughout the century [2]. Among such schools with university-like education, we can point The Royal Academy of Science and Arts of Barcelona (*Reial Acadèmia de Ciències i Arts de Barcelona*, or RACAB, 1764 to present day), The Royal and Military Academy of Mathematics (*Academia Real y Militar de Matemáticas*, 1720-1803), The College of Surgery of Barcelona (*Colegio de Cirugía de Barcelona*, 1760-1843) and The Commerce Council (*Junta de Comercio*, 1769-1851) [3]. The latter had subdivision schools like the Nautical School, Arts School and others. One of these was the Experimental Physics School, set up in 1814, transformed into Experimental Physics Applied to Arts in 1840 and finally in 1851 it became the Industrial School of Barcelona (*Escuela Industrial de Barcelona*), which was the core of present-day Polytechnic

University of Barcelona (*Universitat Politècnica de Barcelona,* UPC), created in 1971 as a result of grouping together all Technical Schools [4].

In 1835, negotiations for returning the university to Barcelona finalised successfully, some chairs were created and the definitive restoration was concluded in 1842. It is interesting to note their different locations. After the aforementioned return some courses were in the Old *Convent del Carme*, until it was burnt down in 1835, and later in 1838 some sections were in the Convalescence House (dependent on the Santa Creu Hospital), all these buildings near the Ramblas. As there was insufficient space, although the original idea for the expansion was the construction of the new building in the place of the old *Convent del Carme*, the definitive location was in today's Plaça de la Universitat. The First Stone was laid in October 1863, and in December 1871, official inaugural lecture in the new building opened the academic year [5].

The collection of scientific instruments and its origins

The University of Barcelona dates from 1450, but the first evidence of experimental physics appeared in 1764 when a group of science enthusiasts gathered together in order to found the Experimental Physics-Mathematics Conference. In 1765 it was recognized by the central government in Madrid with the title of Royal Conference and later, in 1770, it became the aforementioned The Royal Academy of Science and Arts of Barcelona (*Reial Acadèmia de Ciències i Arts de Barcelona*, or RACAB) [2], aforementioned. Although in the 19th century the professors of Experimental Physics of the University of Barcelona were also members of the RACAB, there is no evidence that any instruments were shared in both centres.

The presence of instruments for teaching Physics in the mentioned schools and in the restored (in 1842) University of Barcelona was a consequence of the fact that at that time there was in all Europe a progressive trend towards teaching through experiments because observation was thought to be the best way to learn science. Moreover, scientific knowledge and experimental activities were conceived as crucial from the pedagogical point of view.

In 1846 a step forward was taken in teaching by the Minister Pedro José Pidal Carniado (1799-1865), who conceived new curricula and syllabuses and wrote a set of rules and recommendations regarding the content and organization of the different studies and academic years. This reform is important because it is the beginning of a standardisation process (and at the same time control) of the operating system and teaching activities in all Spanish universities. Later in 1857, the reform of studies by the Minister Claudio Moyano Samaniego (1809-1890) divided the two sections in the Philosophical Faculty of the University of Barcelona into two faculties, *Ciencias* and *Filosofía y Letras* (Science and Arts) [6]. Among the several rules of the mentioned 1846 Pidal reform, appeared a list of recommended instruments for teaching Physics, which we will look at later in more detail.

For this reason, at that time the University of Barcelona acquired the first instruments for the teaching of Physics, which increased notably until the end of the century and continued to do so since then. So over a period of about 150 years the Faculty of Physics has been accumulating scientific instruments for research and teaching.

Among scientific subjects in the Science Faculty were: Rational Mechanics Imponderable fluids (heat, light, electricity and magnetism), later Physics and Superior Physics, Experimental Physics, Extension of Experimental Physics, besides other related subjects such as: Mathematics, Astronomy, Chemistry and Natural History. Among the subjects taught, those of General Physics and Experimental Physics were always present in all the different syllabuses.

Summarizing, all the instruments are associated with the research of particular areas within the physics departments and also associated with practices and experiments corresponding to the experimental sessions. The continuous renovation and substitution led to the storage of the instruments. Unfortunately, no special regulations concerning the obsolete instruments were in force, which meant that storage conditions were very poor and in several cases the instruments were partially dismantled. Moreover, the continuous changes of departments and laboratories within the building, and later the fact that the complete section of the Physics department moved in 1969 to a new building in Diagonal Avenue [7], facilitated a dispersion of instruments and components. As a result of this constant to and fro-ing, the instruments suffered enormously.

Fortunately, between the mid eighties and the late nineties the restoration among the best preserved instruments was carried out, leading to a group of approximately fifty scientific instruments in good state and working order, which are now in five glass cabinets in the Board Room of the Physics Faculty. At the beginning of the new century, a new period of restoration began, thanks to an agreement with the *Escola d'Art i Disseny de la Diputació de Tarragona* in Tortosa and a continuous programme of restoration is currently under way [8]. In 2009 an inventory and cataloguing of 200 instruments was carried out thanks to the help of the project HAR2008-02580-E/HIST. Finally, it is important to add that, although in 1987 there was a project of creation of a University Museum, it was never consolidated, but in January 2010 a Virtual Museum of the University of Barcelona was inaugurated[1].

A review of different lists of instruments

Among the novelties in the aforementioned reform of the minister Pedro José Pidal, a Circular appeared on 15 October 1846 published in the Boletín Oficial de Instrucción Pública with a Catalogue-Model of the machines and instruments necessary for a Chair of Experimental Physics. This catalogue contained 153 items and with the information of the price in FF (French Francs) taken from the catalogue of the maker Lerebours and Pixii from Paris[2]. Similarly, one year later a Catalogue-Model of the Physics-Chemistry instruments necessary for experiments in the provincial Institutes of Secondary Teaching, containing 116 items appeared in the *Real Orden* of 10th April 1847 published in the *Boletín Oficial de Instrucción Pública*.

By analysing both lists, some differences are evident: In the second case, the instruments were grouped in the different fields, whereas no subgroups appeared in the former. Although the number is not the same (153 and 116), in the first group some items were repeated or even redundant (e.g. different types of thermometers or manometers). In the second group an attempt to economize was evident, as can be seen by the smaller number of items and the lesser total value (5000 to 9531 FF), which is also logical if we consider that they were conceived for experiments in provincial Institutes of Secondary Teaching. By classifying the instruments of the first case, both lists are summarized in Table 1, in that the differences are only in a small reduction of elements in each group.

Table 1.

GROUP	1846 LIST	1847 LIST
Hydrost, Hydrodyn, Pressure, Heat, Molecular actions	64	48
Mechanics	23	14
Electrics and Magnetism	42	39
Optics and Acoustics	24	15
TOTAL items	**153**	**116**
Total cost (FF)	**9531**	**5000**

In the archive of the University of Barcelona there is a document with an inventory of 377 items contained in a 'List of equipment and objects in the Cabinet of Physics of the Faculty of Sciences', handwritten and signed by Professor Antonio Rave, on Barcelona, on June 1868[3]. The contents of this list is shown in Table 2.

[2] See page 548 of the site: http://books.google.es/books?id=kLmnLI8xOesC&pg=PA64&dq=boletin+oficial+de+instrucci%C3%B3n+p%C3%BAblica+15+enero+1846&hl=es&ei=dNNwTcTXK87oOdH8sL4G&sa=X&oi=book_result&ct=result&resnum=1&ved=0CDMQ6AEwAA#v=onepage&q&f=false

[3] Archive of the Universidad de Barcelona, ref.: ES CAT-AUB 02 25/2/7/4.

Table 2.

Contents of the 1868 inventory	
Fields	**Items**
Mechanics and gravity	26
Hydrostatics and Hydrodynamics	34
Pneumatics	27
Capillarity and Molecular actions	9
Dilation and thermology	20
Vapor and Hygrometry	24
Heat Radiant and conductivity	18
Heat and Pyrogeny	11
Magnetism	10
Static Electricity	50
Dynamic Electricity	42
Optics	53
Acoustics	26
TOTAL	**350**
And glass containers and tools	27
TOTAL	**377**

A first overview of the lists

An initial hypothesis was that this 1868 list should be similar to Pidal's both lists. As a first approach, if we look at the 'optics' subgroup and the ratio to total items, we can see an agreement in the following percentages in table 3.

Table 3.

List	Total items	Optics items	Percentage
1846	153	21	13.7 %
1847	116	12	10.3 %
1868	350	53	15.1 %

If we compare the contents of the different fields of the 1868 inventory with those of the 1847 Pidal list, we can identify 93 instruments (from a total of 350) as seen in table 4.

Table 4.

Group	1847 List	Common items in 1868
Hydrost., hydrodyn., Press., Heat, Mol.actions	48	35
Mechanics	14	13
Electrics and magnetism	39	30
Optics and Acoustics	15	15
TOTAL	**116**	**93**

The coincidence of 93 elements over 116 gives a good agreement and a percentage of 80.2%. This shows that the instruments registered in the 1868 inventory were based on the recommended Pidal list.

But if we look at coincidences or agreements between the elements of the 1868 inventory and the present collection, we find only 56 identified elements (and some of them with some uncertainty). The reason for this small number is clear, because the present collection has a large number of elements acquired later than 1868. Moreover it is very likely that a good many of the old instruments have been lost, and especially if we consider the changes of locations of the University between 1842 and 1872, the lack of conservation protocols, etc.

A step forward in the study of the present collection was done by analyzing the makers of the scientific instruments.

A look at the makers of scientific instruments

In the initial Pidal recommended Catalogue-Model of machines and instruments, only the French makers Lerebours and Pixii appeared. Noël-Jean Lerebours (1761-1840) made telescopes from 1799. Later, Marc François Louis Secretan (1804-1867), professor of mathematics in Lausanne, settled in Paris in 1844 where he became a partner of the instrument maker Lerebours. This firm was located at 13, Place du Pont Neuf, Paris and later (ca 1840-ca 1855) 23, rue de l'Est, Paris. Nicolas Constant Pixii (1776-1861), and his son, Antoine-Hippolyte Pixii (1808-1835) were at 2, rue du Jardinet, Paris (1818-1838), and later (1838 - 1855) at 18, rue de Grenelle, Saint Germain, Paris.

It is interesting to wonder why only these two makers were recommended if we consider that at the same time the following makers were established in France: Louis Bréguet (1804-1883), Antoine Bréguet (1851-1882), Jules Carpentier (1851-1921), Charles-Félix Collardeau-Duheaume (1796-1869), Jules Duboscq (1817-1886), Eugène Ducretet (1844-1915), Nicolas Fortin (1750-1831), Paul-Gustave Froment (1815-1865), Henry-Prudence Gambey (1787-1847), Marie Amédée Louis Jobin (1861-1945), Alexis Magny (1712-1777), Heinrich-Daniel Ruhmkorff (1803-1877), Jean-Baptiste François Soleil (1798-1878), Louis Joseph Deleuil father (1795-1862), Jean Adrien Deleuil son (1825-1894), Jules Salleron (1829-1897), Jules Dujardin (1857-1947), Rudolph Koenig (1858-1901)[4].

Grouping and comparing the instruments by makers

If we look at the makers of the present collection, among the 200 in the catalogue, we find in the following table 5:

Table 5.

Catalogue of 200 instruments of the present collection		
Unknown makers	54 instruments	
Signed Foreign makers	134 instruments	Corresponding to 93 different makers
Signed Local makers	12 instruments	Corresponding to 10 different makers

The local signed makers are: Anglo Española de Electricidad, Arriete Dalmau y Brunet, Arriete Dalmau Barcelona, Balanzas Cobos Barcelona, Fábrica de instrumentos de precisión Bastos y Laguna, Dalmau Montero constructores de aparatos de precisión, P. Agustí Barcelona, Productos Eléctricos JAC Barcelona, Sociedad Anónima Prieto Barcelona, Vda. de J. Rosell Barcelona. Although these local makers, all of which are from Barcelona except Bastos y Laguna (from Zaragoza), have not been studied in detail yet, but at first sight they seem to belong to a later period than 1868.

Another analysis has been made comparing the instruments of the 1868 Rave list. Among the present instruments (200 catalogued and 100 yet uncatalogued), 56 of them have been identified from the 1868 list. Among them, 9 correspond to signed makers, 26 belong to unknown makers among the collection of 200 but other 21 have been identified among the list of 100 uncatalogued instruments. All these results are summarized in the graph in Figure 1.

---

[4] [12] The makers can be seen in several web sites, such as:
http://iuhps.org/refertxt/catalogs.htm of the Scientific Instruments Commission,
http://www.hasi.gr/makers of the Hellenic Archives of Scientific Instruments,
http://www.bibliotheque.polytechnique.fr of the Bibliothèque Centrale Polytechnique,
http://www.sil.si.edu/digitalcollections/trade-literature/scientific-instruments/CF/SIcompany-names-drilldown.cfm of the Smithsonian Institution libraries.

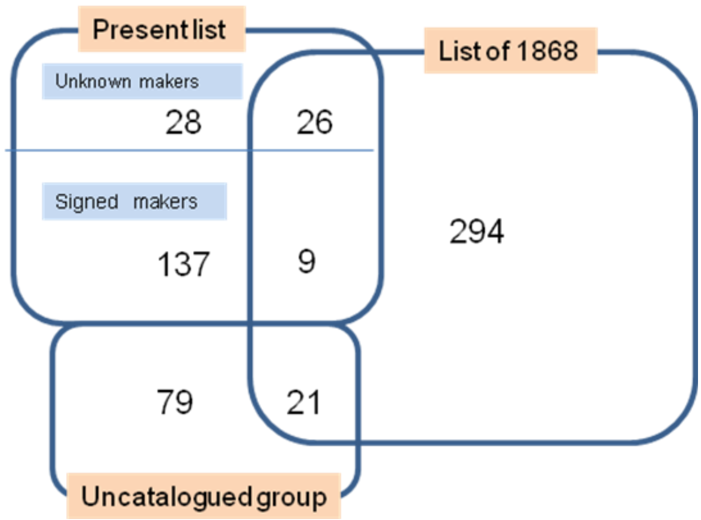

Fig. 1: Graph of the classification of the 56 identified instruments of the 1868 list.

The list of 9 identified instruments (see Figure 2) that corresponds to the known makers is listed below. (In brackets there is the date of birth and death):

a) Mirrors for light recomposition, by Deleuil, senior (1795-1862)? or son (1825-1894)?
b) Camera lucida, by Deleuil, senior (1795-1862)? or son (1825-1894)?
c) Bertin switch, by Ducretet, Eugène (1844-1915).
d) Pneumatic pump, by Pixii senior (1776-1861) & son (1808-1835).
e) Glass tubes for gas experiments, by Pixii senior (1776-1861) & son (1808-1835).
f) Solar microscope by Salleron, Jules (1829-1897).
g) Ruhmkorff coil, by Ducretet, Eugène (1844-1915).
h) Galvanometer of sinus or tangents by Salleron, Jules (1829-1897).
i) Atwood's machine, Gerboz, Pierre (instrument probably released on 1885).

By considering the dates, except the last one, all these instruments could belong to the 1868 list.

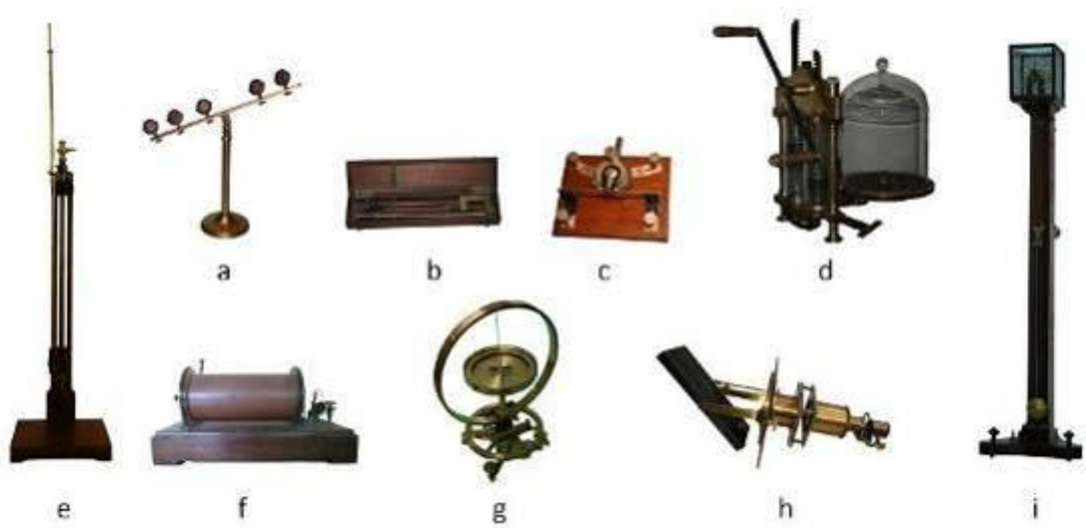

Fig. 2: Probably the oldest identified instruments with known makers.

But the interesting fact is that most of the coincidences (47 instruments) from the 56 identified instruments from the 1868 list correspond to unknown makers. This opens up the possibility that some of these unsigned instruments could have been made by local artists or artisans. As an example, the parabolic reflector for heat and sound experiments has no signature, but is very similar to that item drawn in the Lerebours catalogue, as seen in Figure 3.

Fig. 3: Unsigned parabolic reflector; and a page of the Lerebours catalogue.

Conclusions

The origins of the collection of scientific instruments of the Faculty of Physics of the University of Barcelona, and the influence of the political background have been described. As a basis for the study, a list recommended by the Ministry of Education, that is the Catalogue-Model of machines and instruments necessary for a Chair of Experimental Physics, published in 1846 and 1847, has been considered and also an inventory found in the archives of the University, written in 1868 by professor Antonio Rave. This 1868 list agrees with the recommended lists and moreover, there is a marked increase in the number of items. From this list, few instruments have been preserved to pesent day. Very few instruments from the 1868 list have been correctly identified. There are today only two instruments with the Pixii signature and none with that of Lerebours.

About half of those with no maker's signature were probably made by local makers. The analysis opens a door to the study of local makers or craftsmen.

LES MAGICIENS DE LA LUMIÈRE (*WIZARDS OF LIGHT*): A FILM FOR EDUCATION

Pierre LAUGINIE
Faculté des Sciences d'Orsay, Université Paris-Sud, FRANCE
pierre.lauginie@u-psud.fr

Abstract

This paper explores some uses of the film Wizards of Light *in the field of Education. Examples are given, ranging from junior high schools to undergraduate university level, with special attention to technological education and History of science teaching.*

Introduction

Les Magiciens de la Lumière or *Wizards of Light* is a history of science film (DVD format, 60 min., in French with English or French subtitles) tracing the history of the speed of light up to Foucault's spinning-mirror experiment (1862), a story closely related to the history of Astronomy. It focuses on Foucault's famous spinning-mirror experiment in 1862 which was an important item of our experimental approach of History of Science in Orsay. But other main characters of this enlightening story also appear or are evoked: Galileo with his lanterns, Römer and Cassini debating about Jupiter's moons, Bradley and the stellar aberration, Fizeau and the toothed-wheel experiment, Le Verrier, Froment and others. The main issue is to give an insight on the way in which science is conducted in its historical and social context. The film is a historical work of fiction, with professional actors, directed by the SCAVO[1] with the collaboration of the GHDSO[2] (see Appendix for details).

The DVD of the film is supplemented by a second DVD (DVD-2, "bonus"), in view to make the whole set a tool for Physics education. Included are:

- three filmed sequences: a long interview of William Tobin, author of *The Life and Science of Léon Foucault* [23, 24]; a *Science Café* during which "good questions" are answered by the scientific authors; a scene with modern students in Orsay repeating the spinning mirror experiment;

[1] Service de création audiovisuelle de la faculté d'Orsay.

[2] Groupe d'Histoire et de diffusion des sciences d'Orsay.

- an important printable documentation (PDF, 70 pages) available at the root of DVD-2. Included are: a history of the speed of light; a detailed description of the experiments shown in the film; a very complete glossary of technical and proper names; and an exhaustive bibliography.

One can consider three levels of understanding of the full document:

- at the ground level, the film itself, a cultural approach;
- at the second level, the three filmed sequences in DVD-2 giving a deeper insight on the subject;
- at the third level, the printable PDF-documentation in DVD-2, giving complete scientific and historical details useful, for example, for an educational use.

Both DVDS are distributed in a single package by the SCAVO-Université Paris-sud (see Appendix for information). The target level is from the end of high school to undergraduate university studies. They will equally interest institutions popularizing science, particularly science museums, and all age groups curious about how science is conducted.

In this article, we focus on the use of the film and its "bonus" in Education. We shall only suggest examples of uses in secondary and higher education and in technological courses – a non-exhaustive list; further, we shall examine more precisely the uses of the film in order to illustrate some concepts and aspects of History of science. We strongly emphasize that DVD-2, specially its printable documentation, is essential for an educational use of the film.

A brief history of the speed of light

Light has not always got a *velocity* through History, and this is rapidly evoked in the film. The question of its *instant-propagation* was already debated during the Greek Antiquity, and the conclusion –excepted Empedocles from Agrigento– was generally that the luminous phenomenon was instantaneous [17]. Nevertheless, during the Arab Golden Age, Ibn-al-Haytham (or al-Hazen, 965-1039) places great emphasis on the fact that light is a "body" and that it requires time to travel from the luminous object to your eye [18].

The debate will only resume during the first half of the 17th century, with Descartes and Galileo, two completely opposite approaches. Descartes is inclined to an instantaneous propagation, together with a "successive motion" in space, a rather ambiguous position. Galileo, on the other side, proposes –the first through History– an experimental test (shown in the film) to decide. Of course, he cannot conclude anything [13], but it is a completely innovative approach!

The solution will come from Astronomy. Discovered by Galileo in 1610, Jupiter's moons, providing people with a "perfect" clock in the night sky, are expected to solve the puzzling problem of longitudes, on dry land and specially at sea. Indeed, the longitude at sea was, in the beginning of the 17th century, a completely unsolved problem, responsible for many wrecks and thousands of sailors' deaths. Practically, to determine your longitude, you need a timekeeper giving the time at some fixed reference meridian and you get the longitude from its time difference with your local solar time. But no accurate clock available at the time! Thus, an intense activity in accurate observations of Jupiter moons started immediately. Jean-Dominique Cassini's ephemerides of Jupiter's moons, published in 1668, required 15 years of hard work at San Petronio's gnomon in Bologna. Though impracticable at sea from the moving deck of a ship with Galileo's telescopes, the method is excellent on *terra firma* and it will be used during two centuries for terrestrial longitudes.

A problem initially reported, but not interpreted, by Galileo, was that the motion of Jupiter's satellite Io around the planet didn't seem so regular as it should according to Kepler's laws. Furthermore, those irregularities seemed more or less correlated to the motion of the Earth. Compiling a large set of observations, Römer, in a famous paper in the *Journal des scavans* in 1676 [19, 20], explained that, granted that light requires time to come from Jupiter to us, the observed irregularities are accounted for (related in a scene of the film). He estimated a time of 22 minutes for light to cross the diameter of the Earth's orbit. Römer didn't immediately convince all his colleagues except Huygens, and Cassini himself – though actual initiator of this interpretation– was particularly reluctant to his conclusions, with some good arguments [3].

The situation will rapidly evolve with the *Traité de la lumière*, published by Huygens in 1690 but written well before, around 1678 [15, 3]. Huygens develops a wave theory of light similar to sound waves, and he absolutely needs a finite velocity, however high it may be! Thus, preceding any reflections about the nature of light, Huygens explicitly deduces from Römer's data a numerical value of the velocity of light "more than six hundred thousand times larger than that of sound, which is not at all the same thing as being instantaneous, since there is the same difference as between something finite and something infinite" (trad. in ref. [3]). For the first time, the word "velocity" is explicitly employed concerning light.

The scientific community will be definitively convinced of the finite speed of light only with the discovery of the stellar aberration by Bradley in 1728 [4, 16]. Once again, the solution came from a completely unexpected way. After looking for stellar parallaxes for years, which were expected to bring an observational proof in favour of Copernicus but were yet too small to be detected, Bradley discovers stellar aberration: a new small annual elliptical motion of all the stars. From which, given the accepted Earth-Sun distance, the velocity of light can easily be deduced. Similarly to Römer, Bradley doesn't produce any numerical value for the speed of light. However, the value one can deduce from his data reveals to us the high accuracy of his measurements.

Thus, in the first third of the 18^{th} century, from astronomical works, light has, in the end, got a velocity, and its value is quite close to the modern one. Things will remain roughly unchanged until the middle of the 19^{th} century.

The really *new* fact will be the possibility of *terrestrial* measurements of the speed of light, first evidenced by Fizeau in 1849 [7] with the toothed-wheel experiment between his attic in Suresnes and a mirror placed on Montmartre hill, 8 km away (an important scene in the film). Although not more accurate than the astronomical ones, this measurement is the starting point of a revolution: reversing the reasonings from which the velocity of light was deduced, (Jupiter's moon or stellar aberration), an *independent* value of the velocity of light, combined either with the period of Io or with stellar aberration, yields the mean Earth-Sun distance, a major astronomical problem for two centuries! And, as pointed by Arago, laboratory tools can be almost indefinitely improved [1]. Furthermore, contrary to the planetary parallaxes previously in use, the result no longer relies on the shape and size of the Earth. And so will the nearby stars distances be measured anew by Bessel from *stellar parallaxes*.

Thus, with Foucault's 1862 measurement –the first *accurate* terrestrial measurement in air– the scientific status of the velocity of light has undergone a dramatic change: while an item of intellectual curiosity for a long time, it becomes now the new standard for the measurement of the solar system and, beyond, the Universe (further details in DVD-2).

The film in Technology Education

Actually, the first use of the spinning mirror technique by Léon Foucault was not for an absolute measurement of the speed of light in air. In 1850, following a suggestion by Arago, he performed *a comparison* of the velocity of light in air and in water. Indeed, it was believed for long that, if light was a *body* (i.e. corpuscules or "emission" model), its velocity should increase in dense materials; conversely, if it was an *undulation* (waves), it should decrease. Following Foucault's result (a decrease) the "emission" model –as conceived at the time– was falsified [8, 9]. This experiment is evoked in the film.

Twelve years later, the French astronomer Le Verrier will urge Foucault to perform an *accurate* measurement of the velocity of light in order to corroborate his own calculations of the solar parallax, or Earth-Sun distance. Perfecting his previous spinning mirror and driving system, Foucault will obtain a very improved value, in full agreement with Le Verrier's calculations (the "final experiment" in the film) [10, 11].

One can take advantage of this story in Technology education:

- the 1850-experiment: why did Foucault beat his colleague and competitor Fizeau in the air-water experiment ? Likely due to his choice of a pneumatic drive (a small turbin) for his rapidly spinning mirror, instead of the heavy clock-machinery used by Fizeau. We emphasize that such pneumatic drives remain nowadays the best choice when you need to rotate very quickly a small object (example: solid-state NMR requiring several kHz spinning).
- the 1862-experiment: contrary to the 1850 one, the purpose of which was qualitative and "epistemological", the 1862 experiment is typically a work of *Metrology*. In such an experiment, nobody knows in advance the "good" result (except, maybe, in this particular case, Le Verrier!), and the technical constraints are quite different: accuracy is the main goal. Thus, it appears interesting, in a Technology course, to show how the initial experiment has evolved from a *qualitative* concern to a *metrological* one, with the *same* physicist, using the *same* principle of experiment and the *same* spinning mirror:
    - *improving the turbine*: 16 injection holes instead of 2, use of Aluminium for improving the axle equilibrium, and applying a new design of the blades according to the last mathematical developments will allow to reduce the necessary pressure to 30 cm of water column instead of half-atmosphere of steam (5 metres of water column). Let us hear the academician Girard: "applying this (new) principle, *I designed the blades* of the small turbine for Mr Léon Foucault … and his new experiments have shown how this small motor drived the mirror with high steadiness requiring only a very low air-pressure, as a consequence of its good-design" [14].
    - *improving the efficiency of the fluid*: replacing steam (373 K) by compressed air, more dense and colder (290 K), thus more efficient, and eliminating condensation problems; special bellows built by Cavaillé-Coll, the famous organ builder, to drive the turbine; accuracy of the pressure: 0.2 mm for 30 cm of water column.
    - *improving the adjustment and* measurement *of the rotational velocity of the mirror*: design of a special "stroboscopic clock" by Froment, instead of the 1850-diapazon; velocity stability: 1/10 000 "for minutes".

Some uses in secondary Education

1. In junior high schools: Galileo's lanterns

Though the theme of the film is a bit difficult for very young children, ask them to play the scene with Galileo's lanterns, using, of course, true lanterns with true candles: sure, you will get a clear success! Of course, they will not "measure" the speed of light, but they'll understand easily Galileo's procedure, specially: why did Galileo ask the protagonists to proceed at first *very close to one another?* Evidently, he aims at *calibrating the response time* of the experimenters. And young children can try this!

In order to get an evaluation of this response time, you can ask children to sing, at least to sing the scale! Remember that Galileo was a good musician and he used to measure time intervals by beating time while singing! If your children are reluctant to sing, they can at least "speak" the scale. And you get the correct answer: the response time is about the time for "C-D", say 1/10 to 1/5 of a second. Then you can develop any commentaries about this experiment, about the "science landscape" at Galileo's time, about Galileo's life and works and his place in History of Science.

2. In higher level high schools: Römer and Jupiter's moons; Bradley and stellar aberration

Both scenes in the film afford support to elementary demonstrations.

Jupiter's moons: improvise a short play aiming at making clear the phenomenon interpreted by Römer, "the man who discovered the finite speed of light": a broad-shouldered pupil, keeping still at the centre, is the Sun; the teacher is the Earth, slowly rotating about the Sun; at about five times the Earth-Sun distance, another –strong– pupil is Jupiter; a very light girl is Io, rapidly twirling around Jupiter. You explain it all!

Stellar aberration: explain what aberration is using analogy with falling rain, using an umbrella on a rainy day; ask children to run under the rain! Then, again with a still Sun at the centre, the teacher –pointing to a virtual star with a stick and moving around the Sun– shows how the stellar aberration results in a small ellipse described in one year by the star [4, 16]. From which the speed of light!

The film at University level

We shall here suggest only two specific uses, quite adapted for undergraduate students. The specific questions of History of science will be examined in the next section.

The spinning-mirror experiment: repeat Foucault's spinning mirror experiment. Modern adaptations are necessary –it is not a replication– but *in full respect of the main characteristics of the original experiment*. What do we intend? Of course, the heliostat can be replaced by any source (e.g. a laser) and the organ bellows drive by an electric motor displaying its rotation velocity: what you need is light, and to rotate the mirror, anyhow. On the other hand, the sizes of the mirrors, the rotational velocity and the order of magnitude of the distance between the two mirrors should be respected. Performing the experiment *à la Foucault* is an excellent approach to the story of the speed of light!

Römer's discovery and light models: An interesting discussion! Ask students to retrieve implicit models of light embedded in historical interpretations. For example, from Römer's data, Huygens deduces an explicit value of the speed of light, simply dividing the distance by the time : 22 minutes to cross the Earth's orbit. Is the result model-dependent (waves or particles)? Frame of reference dependent? In the classical wave model –including ether– shouldn't you need to know the Earth's velocity *relatively to ether*? Is it large? Null? Nobody knows. Huygens –the father of this classical wave model– ignores the question. Discuss that.

The film as a tool for History of Science teaching

Wizards of Light can be used as an excellent support for introducing some concepts of History of Science. We give below some tracks.

1. The speed of light as a side-effect of the longitude problem

As related in the second section of this paper, the finite speed of light was a quite indirect and unexpected consequence of the long search for a tractable solution to the problem of longitudes at sea (for a general public survey of this problem, see [21]).

From 1669, Cassini –the best expert in terrestrial longitudes based on Jupiter moon periods– is called by Colbert to the newly built observatory in Paris. There, he will soon encounter Picard, La Hire, Richer and Huygens –also called by Colbert as an expert in longitudes at sea– and the Danish Ole Römer. This is, maybe, the first example of a *planned research* program initiated by the State top authorities. Cassini comes with his newly published ephemerides of Jupiter moons, and what happens? As we know, the finite speed of light will unexpectedly result from the detailed studies of the satellites irregularities. We emphasize that, though the name of Römer remains attached to this discovery –likely due to his determination in supporting his interpretation– it results of the works of the whole crew of the Paris Observatory [3].

This is a very significant example of how science is conducted, mixing formal debates, theoretical models, planned research and chance, a very enlightening story: at first, a millenary formal debate implying most great philosophers and peaking with Descartes; on the other hand, at the beginning of the17th century, from practical needs of sailors, a long search for solving the longitude problem. The Jupiter moons discovery came just "by chance" as yielding a potential solution, unusable at sea but of great interest on dry land. Completely unexpectedly, the demonstration of the finite velocity of light will result. Such a transposition of a formal debate to the sphere of observational Astronomy makes the speed of light a component of what is usually accepted as the "scientific revolution" of Modern Ages.

2. The speed of light and the concept of infinity

There is some relationship between the speed of light and the concept of infinity which, as we know, was debated at the 16th and 17th centuries. The millenary questioning was: does light require time to travel from the observed object to our eye? Should we translate, in modern terms: "does light have a finite velocity"? Certainly not. And this is important in teaching History of science: we are continuously threatened by anachronisms!

The best example is with Descartes: a "successive propagation in space of a *tendency to motion* requiring no transport of matter", and nevertheless "out of time" as it appears from the parable of the stick and the blind man, and in the example of lunar eclipses. Furthermore, for Descartes, light propagates "more easily" in dense materials (water, glass) than in air. Should we translate by: "more rapidly", and consequently "with a velocity greater than infinity"? Obviously not. In addition, in a letter to Mersenne, Descartes maintains it "contradictory that an infinite velocity might exist in Nature" [5]. Thus, we shouldn't apply to Descartes' times our modern concept of velocity in the meaning of dimensional analysis, i.e. a length divided by a time. Good lesson!

In a history of science workshop, you can ask students to compare the practical definitions of "instant propagation" in Galileo and in Descartes, who worked roughly at the same times. A detailed examination of the text of the "Two lanterns" (scene in the film) and of Descartes' example of lunar eclipses, leads to the following conclusion: it is considered as "instant propagation" a motion in space too fast to be detected by our senses on usual tractable distances i.e. two or three leagues. This would mean, *for us*, that a velocity is considered as infinite if it is greater than, say, 100 km/s. And, curiously, the same order of magnitude is obtained either from Galileo or from Descartes. No "actual infinity", not even "potential infinity", just a step on the way of potential infinity.

We may remark, however, that a clear definition of "actual infinity" is given by Galileo in his "Two new Sciences" (a set that is isomorphic to one of its parts) and that, half a century later, Huygens' conclusions (above reported, second section) about Römer's data, imply the acceptation of an "actual infinity". This is well in the filiation of Bruno, and in clear opposition to Aristotle.

3. Motivations of a measurement

Following the film, you may ask students a reflection about the motivations of a measurement in Physics, and more generally in Science.

- In order to make a measurement, you need, at first, *something* to be measured. Concerning the speed of light, our story shows that it was not the case during many centuries. Following this millenary debate, the conclusion about the finite speed of light came only with Römer (1676) and Bradley (1728) as shown in the film.
- Once there is something to be measured, why should one measure it? The question is so less evident that neither Römer nor Bradley published an explicit value of the speed of light, even if it can easily be deduced from their data. Why? Actually, it was sufficient for them that the finite speed of light solved their problem: the irregularities in the period of Io and stellar aberration respectively. The explicit value of such a fantastic velocity didn't enter any theory nor any problematics and had no application. Indeed, the velocity of light will remain a matter of scientific curiosity until the middle of the 19th century.
- Thus, around the middle of the 19th century, the new feasibility of terrestrial measurements first evidenced by Fizeau [7] will, at last, renew the interest in the speed of light. The first measurement by Foucault in 1850 (evoked in the film), comparing the velocities of light in air and in water, was a *qualitative* one: to decide between two rival theories. This is a special type of motivation.
- On the other hand, the 1862 experiment, again by Foucault, was an accurate experiment of *Metrology*, strongly required by Astronomy. As shown in the third section of this paper, the motivations and the constraints are totally different! This experiment will give the speed of light a new theoretical and practical status: a standard for measuring distances (cf. second section). And the film ends on the suggestion that this velocity might be "independent of all".

The film and general public

With general public, for example in science festivals, any question can arise! They are so various that you cannot expect to predicting any. Be only ready, and be modest: remember that you are allowed not to know all and you can be unable to answer some questions. Avoid lengthy answers and one-to-one controversies about very specialized questions: think that you don't only have to answer the questioner, but your answer should arouse the interest of the whole audience. This is particularly true for questions about Relativity paradoxes or the basis of Quantum Mechanics, such questions – somewhat beyond the subject of the film– always arise! Apart from this reservation, all questions are welcome and the debate can be extremely rich.

AN AIM FOR SCIENTIFIC EDUCATION IN FRANCE: THE IMAGE OF THE NATURE OF SCIENCE. THE CONTRIBUTION OF THE HISTORY OF SCIENCE IN PHYSICS COURSES

Laurence MAURINES, Daniel BEAUFILS
DidaScO, Université Paris-Sud 11, FRANCE
laurence.maurines@u-psud.fr

Abstract

Physics and chemistry programs at the secondary school level in France recommend introducing components of the history of science as well as investigative activities. These two aspects are the result of an implicit general goal of these programs related to the representation of the nature of science and scientific inquiry. We first demonstrate how our historical and epistemological analysis led us to distinguish different learning goals associated with different points of view about science. We then show how these goals can generate classroom activities involving collective inquiry that is based on the implementation of "historical" documents which may or may not be paired with experiments. The approach used in some of our proposals is innovative: the reading assignment of the kit of documents is divided among all students and the synthesis consists in collectively drawing a diagram providing a synoptic visualization of the epistemological objective. Finally we discuss the tensions that our choices created among teachers.

Introduction

For several years, the introductions of the French science programs recommend to introduce the history of science (HS) at all levels of teaching[1]. Emphasis is placed on a "cultural" dimension which is poorly defined but essentially refers to elements of epistemological nature. By the same token, these introductions recommend approaches that are based on student inquiry. Although implementing these pedagogical situations satisfies above all the concern of familiarizing students with scientific process skills and attitudes as well as giving them better mastery of scientific concepts, this strategy also refers to the image of the nature of science and scientific inquiry. But in both cases the epistemological dimension of scientific

[1] For example, see the introduction of the high school science program: B.O. (2008).

education is more suggested than explicitly stated. The targeted level of competencies never addresses the issue of the representation of science; it focuses on scientific knowledge and process skills only. Moreover, the programs suggest few examples of activities based on HS: most of them are means to learn scientific content and convey a reductive and false image of science.

Besides, several studies (Guilbert & Meloche, 1993; Robardet & Vérin, 1998; Roletto, 1998; Mathews, 2003; Lederman, 2007; Höttecke, 2010a) conducted in France and abroad demonstrate that science teachers are unaware of the epistemological issue of scientific education. Even those for whom this is a significant dimension tend simply to privilege the acquisition of scientific knowledge and process. These studies also show that many teachers have an outmoded vision of the sciences (empirically inductive and naïvely realistic) and unconsciously convey this stance to their students through the way they teach.

Other studies (Leite, 2002; Mathy, 1997; Beaufils & Maurines, 2008) reveal that textbooks convey a reductive and false image of science, either through the approaches that are chosen, their vocabulary, or their choice of historical elements. These elements refer to only one person who is most often well known and has intuitive genius; they focus on the discovery of the laws of science and their interpretation.

This situation led us to start a research program that examines whether the introduction of the history of science in physics courses can help to address the epistemological issue of scientific education.

Questions explored

The issue of greater authenticity in representing the nature of science in physics classes has three main aspects. First, how do we characterize this authenticity? Can historical examples be found that are compatible with physics curricula and students' academic level? If so, what student activities support these objectives? The first question invites an historical and epistemological analysis. The other two are subtended to the approach taken by experimentation that seeks to develop pedagogical resources and activities that can be assigned to students.

The underlying hypothesis of our research is that resources and activities, which offer a heightened sense of the reality of the nature of scientific knowledge and activity, can provide a broader scientific cultural integration for students and have a positive effect on their relationship with science as an academic discipline. We confer with Solbes and Traver (2003) on that point. This is a significant societal issue, given students' current disaffection with the branches of basic science.

Our position is unique in France: almost all other recent work concerned with the use of the history of science in physics courses (Guedj, 2005; de Hosson & Kaminski, 2007) does not explore this aspect; its goal is the acquisition of scientific concepts. The historical elements introduced in these different studies are minimized (names of scientists, dates) and concern controversies over the interpretation of specific phenomena (vision, the movement of a projectile in a referential that is moving in relation to another, etc.). In English-speaking countries this position, known as NoS —"the nature of science"— has been used for more than twenty years. It allows specific goals of learning on the epistemological level to be clearly stated, as demonstrated by the recent publications of the group of experts working on Project 2061, which was begun in the United States in 1986 by the American Association for the Advancement of Science (AAAS). As we will demonstrate further, this pedagogical stance also allows teachers to create activities that are perfectly defined both from the point of view of the targeted goal and the topic under discussion.

The epistemological and historical framework that we have adopted privileges the individual[2]: from this historical perspective, scientific knowledge is considered to be the result of activities performed by individuals in the socio-cultural context of a given historical period. But these activities do not correspond to ordinary intellectual constructs, since they must follow rules and demonstrative procedures and also be validated by confronting them with the results of observation and experimentation.

Methods

Our work initially consisted of three complementary analyses. One concerned the former and current high school curricula. Another one dealt with old and new physics textbooks in French and English. The third one consisted of an epistemological analysis focused on scientific activity and different approaches (internal and external) taken by history of science. These analyses allowed us to discern different characteristics of science that may be used as temporal invariables and constitute key points of an authentic image of science and scientific activity upon which learning goals may be based *a priori*.

[2] We refer to Mathy (1997) and Gagné (1994) on that point.

These analyses led us to create and design resources and activities for students that were both appropriate to a given level of instruction and fulfilled a specific epistemological objective. Before spreading our pedagogical propositions, we sought to improve them in taking into account teachers' feedback. We contacted various colleagues who had replied to a first inquiry on their relationship to the use of HS in teaching (Beaufils et al, 2010) and expressed interest in receiving complete pedagogical resources. Each dossier was accompanied by a set of questions that allowed teachers to share their reactions to the objectives, documents, type of collective activity, and goal of the assignment (presented as a diagram). On a more general level, we sought an initial opinion of the feasibility of the dossier vis-à-vis the targeted teaching level (especially grade 10). The information returned to us completed the first synthesis of material that resulted from a session of ongoing teacher training and allow us to improve our proposals.

We have arrived at a new stage of our project, which includes trial runs of different resource kits by teachers who have volunteered for the task and the constitution of an informal group in order to adopt a symbiotic strategy in the future (Höttecke, 2010b).

Design of innovative pedagogical units. Epistemological learning goals

Our epistemological and historical analyses lead us to the "consensus view" of the nature of science which comprises a set of aspects widely accepted in standard documents (Project 2061 for example) and philosophy of science (Lederman, 2007). The list below (figure 1) presents some of these characteristics, ranging from the difficulties encountered by scientists to questions about the social dimension of the work as well as the different types of activities and methods and the nature of models, theories, and proofs. These features of science could be chosen to define the goals of introducing the history of science in the teaching of science.

- scientific activity is a nexus of controversy.
- scientific knowledge follows criteria of internal coherence, simplicity, and strength and has to be confronted with facts based on observation and experiments.
- a scientist does not work in isolation but within a community that participates in testing established scientific knowledge.
- there is a strong relationship between technical questions and the evolution of ideas.
- knowledge has evolved over time (through continuity and ruptures).
- there is an interdependence between science and society.
- there are relationships between science and beliefs.

Fig. 1: Some characteristics of scientific activity.

In our opinion, introducing the history of science in science courses highlights episodes of scientific activity of various lengths seen through a series of critical epistemological filters. We would like to observe first of all that since these goals focus on epistemological aspects, they may be independent of conceptual or process learning objectives, which therefore can be only secondary, if not completely absent. This position is close to the one presented by Lederman and Abd-El-Khalick (1998) about activities relating to NoS. This choice obviously creates tensions with teachers' own representations of the teaching of science and their daily teaching practices.

It is also important to note that the choice of an objective such as "showing the interaction between scientists" is obviously a reduction of a historical reality which generally results from many interacting factors. But this reduction is not the same as that which we denounce in the introduction. On the other hand, the idea is that some of these goals are worked at every level of education so that a student has all them discussed at the end of his schooling.

Choice for the elaboration of innovative pedagogical units

Several choices determined the direction of our pedagogical research.

The first one was to pinpoint the field of optics. This choice was the result in part of the area of specialization of our team members and the identification of several "historical situations" that could be integrated into physics curricula from grade 7 to grade 12.

The second choice was based on a didactic position that by general consensus seeks to assign an active role to the student and was to suggest student activities beyond simply providing documentary resources for teachers. We chose to design collective activities that permit complementary or contradictory interactions and the development of shared knowledge, that is to say to integrate them with investigative situations. Concurring with Morge and Boilevin (2007), we define an investigative situation as one in which *students learn by performing tasks that are not exclusively experimental in nature and by taking part in a process of validating their peers' results.*

We designed two types of investigative situations: some pair experiments and texts; others are based only on documents. According to a practice recommended for primary school teaching and also developed in biology and geology teaching at the secondary level, we believe that the documents can be introduced at any time in order to facilitate different tasks, for example in order to state or validate hypotheses related to the nature of science.

We created dossiers on various topics, including kit of texts for students and guideline for the teacher describing the objectives of the activity and how it is to be conducted. The selection of historical material was based not only on primary texts but also on texts written by historians or scientists keen on history. We have even adapted some of them. Indeed, our primary objective is to provide students with texts easy to read. The documents we elaborated present information in different forms —texts, diagrams, drawings, etc.

Experimental investigation

In our first study (Maurines and Mayrague, 2005), following the hypothesis that some teachers prefer situations that link texts with experiments, since they might not want to deviate from their preferred conceptual or procedural learning goals, the reading of historical texts was coupled with doing an experiment described or inspired by the texts. This choice would be useful when asking students to practice science while at the same time foregrounding the historical process of developing knowledge. This approach becomes most meaningful when the targeted goal stresses the process of validating a model by confronting its prediction with facts derived from observation and experimentation; the choice seems artificial, however, and therefore inappropriate in relation to a goal like studying "interactions between scientists."

We outline in figure 2 one possible way of structuring a science lesson on the epistemological objectives "scientists test their explanations against facts that result from observation and experiments" and "scientists valorize those explanations that allow for a large number of facts to be interpreted simply"; to develop the notion that white light is composed of different "colored lights"; and to ask students to practice science taking an experimental approach.

<u>Appropriating or/and constructing a problem</u>

- The presentation of an experiment involving the dispersion of white light through a prism.
- create a conflict: compare De Dominis' and Newton's models.
- state hypotheses inspired by the texts: Is white light homogeneous and are colors created uniquely by the action of the prism?

<u>Resolving of the problem</u>

- develop experiments that allow the hypothesis to be tested, revealing its consequences.
- confront expectations with the results of the experiment.
- invalidate the model of homogeneous white light.

<u>Establishing knowledge</u>[3]

- scientists test their explanations against facts that result from observation and experiments; they valorize those explanations that allow for a large number of facts to be interpreted simply.
- white light is heterogeneous and composed of colored light.

Fig. 2: A possible structural outline of an activity combining texts and experiments (Topic: the dispersion of white light).

[3] Establishing the knowledge collectively constructed by students consists in recognizing that it conforms to the knowledge shared by the scientific community.

In this type of investigative situation, the risk of drifting off course toward an emphasis on knowledge and methods is especially high. It is fundamentally important that the stage of establishing knowledge be related not only to the scientific notions developed but also to the historical process of developing knowledge and to what it teaches us about the nature of science and scientific practice.

But the choice of basing experiments on a historical foundation is problematic: not only does the presentation of knowledge as answer to a problem not require an historical reference, but on the contrary, the historical reference that is introduced to convey a synoptic idea of scientific practice in a particular historical period requires that students put themselves into the conditions and circumstances of scientific and technical knowledge applicable to the historical period in question. This strategy raises the possibility of asking students to comprehend what was actually at stake then—for instance, the ingenuity of a particular approach or the revolutionary nature of an idea in its time and the nature of the historical elements that are introduced.

Documentary investigation

Other resources (Maurines et al, 2009) propose learning situations that we describe as "documentary investigation." These situations are based on kits usually composed of about ten interrelated documents characterized by a "point of entry" that is directly related to the goal to be achieved: this might take the form of scientists' names, for instance, or technical achievements (see examples in Appendix 1). The reading assignment is divided among all members of the class and the synthesis is made in class under the teacher's "guidance". Figure 3 shows a way of structuring the work done in class:

<u>Appropriating or/and constructing a problem</u>

- integrate the topic into the teacher's learning sequence for the class; highlight questions of a historical nature: *how do we know that...?*
- specify a specific problematic that sets the goal to be achieved.

<u>Resolving the problem</u>

Documentary work (as homework or in class, individual or in small groups)

- present documentary resources.
- distribute the documents among the members of the class.
- read documents and prepare the lesson in which the synthesis will be done, guided by instructions that specify the type of information to be culled from the text; who, what, how, why, etc. (in relation to the documents and the question).

Reaching a synthesis (students will do this collectively based on each class member's contribution).

<u>Establishing knowledge</u>

- the teacher generalizes the results that were found by pupils and shows the connection between how science worked in the past and the present situation.

Fig. 3: A possible structural outline of an investigative situation based on historical texts.

Since the reading assignment is divided among all members of the class, the synthesis that is made in class under the teacher's "guidance" is supposed to produce a specific type of result: a diagram (see example in figure 4, another one is presented in Appendix 2) that provides a synoptic visualization of the information that has been gathered and illustrates the targeted goal. The choice of constructing a diagram to represent the synthesis corresponds to the idea that this type of synoptic representation is adapted to our pedagogical goals. In the case of the goal-related scientific attribute "interactions among scientists", it is important actively to resist the image of the solitary scientist who had a stroke of genius; instead, the approach we are proposing will guide students toward the image of a complex interaction that was developed over time.

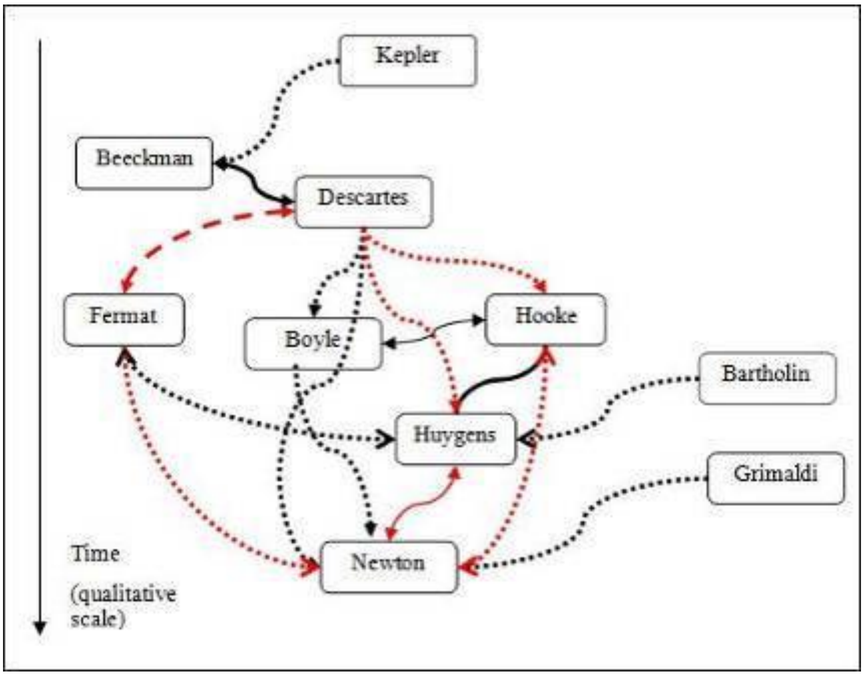

Fig. 4: example of diagram on the epistemological objective "interactions between scientists and the topic "laws of refraction"[4].

First feedbacks from teachers

Some of the "historical" activities that we suggest are innovative in several ways. The issues we propose and their specific goals concern the representation of science and scientific activity and not the mastery of a scientific concept. Our document kits go against the grain of the insets and similar texts included in current textbooks. Our suggested activities involve students collectively. Finally, the goal of these activities is to create and design synoptic presentations, especially diagrams that use semantic networks as a model.

The first kit we elaborated concerns the topic of refraction at the grade 10 level and suggests a documentary investigative situation on the epistemological goal "interaction between scientists". The majority of responses given by the 15 teachers who accepted to send us back the questionnaire on the feasibility of our proposal indicated that the objective was both important and interesting, stressing the fact that the evolution of science, with its complexity and social dimension, should be demonstrated. Responses were largely positive in favor of presenting this kit at the grade 10 level but some colleagues expressed reserve and were concerned that the intellectual level of the students would be overly challenged by documentary activities involving reading that was beyond their critical ability. The answers to the questions on the pedagogical organization range from positive feedback arguing for a simple activity that could be integrated into the complete set of activities students are asked to perform, to negative feedback, arguing that the texts were too difficult, that the synthesis students were asked to make (a diagram) was too abstract, and that the context was too exclusively cultural, independent of notional learning, requiring highly motivated students.

By way of conclusion: some remarks on the teachers' relationship to the history of science in science teaching

From the one hundred and twenty three responses we received (to open and closed questions), we have highlighted two points: 1) their responses to the assistance they expected in integrating the history of science into the teaching of physics and chemistry; and 2) the place of the history of science in academic disciplines.

---

[4] The arrows are different because they are different types of interactions. Continuous double arrow: direct interaction. Dashed double arrow: epistolary interaction. Dotted single arrow: knowledge of the works. Red double arrow: interaction with controversy. Red single arrow: opposition of points of view.

In response to teachers' assistance in introducing the history of science in their courses, we asked them to choose from among five different resource kits: 1) references to Internet sites; 2) a historical bibliography; 3) a pedagogical bibliography; 4) annotated historical documents; and 5) complete lesson plans. More than half the teachers chose two resources, and from among them, the pair "annotated historical documents + complete lesson plans" was a popular choice. That result was a positive affirmation of our project.

One question remained, however, as to the amount of time teachers were willing to devote to the history of science in their courses. If 60% of answers received were very in favour of student activities (documentary group work, for instance) focused on the history of science in the case of an interdisciplinary assignment, no more than 45% were supportive of this type of activity in physics and chemistry classes.

Document DidaScO | *Ne pas diffuser svp*

Dans son ouvrage *Histoire de l'arc-en-ciel*, B. Maitte retrace, depuis l'Antiquité la multiplicité des questions que l'on a pu, à chaque époque, se poser, et auxquelles correspondent autant de descriptions différentes….

Parmi les savants, Robert Boyle, chimiste anglais…

[…]

Ses expériences partent d'un présupposé tiré de Descartes dans une direction autre que celle empruntée par Hooke et Huygens : alors que ceux-ci retiennent l'hypothèse d'un monde plein et sont partisans d'une théorie ondulatoire de la lumière, Boyle en fait un flot de « particules qui composent chaque rayon particulier et parviennent dans l'organe des sens », provoquent des chocs sur la rétine, ainsi que « le *très ingénieux Descartes l'a parfaitement bien supposé* »

Pour Boyle, ces particules arrivent dans un ordre et avec un degré de vitesse différents sur les parties superficielles des corps. La lumière est alors troublée, ce qui fait que nous disons « *que le corps vu est soit blanc, soit noir, soit rouge, soit jaune, soit d'une autre couleur déterminée* » La couleur n'est donc pas inhérente aux corps, mais une propriété prise par la lumière sous l'influence des corps. Est-elle « *un mélange [de lumière] avec des ombres… la rotation des globules célestes cartésiens, ou… quelque autre voie.., je ne prétends pas l'affirmer* ».

[…]

Note : Robert Boyle, scientifique anglais (1627 - 1691) est l'un des premiers adeptes de la méthode scientifique et l'un des fondateurs de la chimie moderne. Il ne s'intéresse guère à la lumière en elle-même, mais aux modifications colorées qu'elle subit en relation avec la composition de diverses substances.

Document DidaScO *Ne pas diffuser svp*

Dans son cédérom Histoire des idées sur la lumière, C. Bracco consacre un chapitre à Christiaan Huygens mathématicien, astronome et physicien néerlandais du XVII[e] siècle.

Spath d'Islande montrant l'effet de la double réfraction (photographie Pierre Thomas – NdR)

Il place deux spaths[1] l'un derrière l'autre. Le faisceau incident est dédoublé par le premier ; les faisceaux émergents constituent deux faisceaux incidents pour le second. Il observe que chacun de ces faisceaux se dédouble en général, si bien qu'il obtient quatre faisceaux émergents comme il pouvait s'y attendre. Cependant ces faisceaux n'ont pas la même intensité et deux d'entre eux s'éteignent pour des orientations particulières du second cristal.

Huygens n'a pas d'explication de ce phénomène et écrit : « … *car bien que je n'en aie pas pu trouver jusqu'ici la cause, je ne veux pas laisser pour cela de l'indiquer, afin de donner occasion à d'autres de chercher. Il semble qu'il faudrait faire encore d'autres suppositions outre celles que j'ai faites ; qui ne laisseront pas pour autant de garder leur vraisemblance, après avoir été confirmées par tant de preuves […]. Il semble qu'on est obligé de conclure que les ondes[2] de lumière, pour avoir passé le premier cristal, acquièrent certaines formes ou disposition… mais dire comment cela se fait, je n'ai rien trouvé jusqu'ici qui me satisfasse* ». (Huygens. *Traité de la lumière*,1690)

Cet aveu d'échec sera un des arguments utilisés par Newton, après la mort de Huygens, pour discréditer cette théorie.

Note : l'application la plus spectaculaire de la théorie de Huygens, savant néerlandais (1629-1695) est l'explication de la biréfringence[3] du spath d'Islande rapportée par Érasme Bartholin[4] en 1669 : ce cristal possède la propriété de dédoubler les images des objets.

[1] Spath d'islande : calcite, carbonate de calcium cristallisé. Quand la calcite est transparente, on l'appele spath d'islande, car les premiers échantillons provenaient d'Islande. Ces cristaux tapissaient les parois de fissures et de cavités rocheuses (geodes).
[2] Voir document Huygens2
[3] Désigne le fait que le materiau provoque deux refractions différentes.
[4] Rasmus Bartholin, ou Erasmus Berthelsen, né à Roskilde le 13 août 1625, était un médecin danois.

Appendix 2: example of diagram on the epistemological goal "relationships between technical questions and the evolution of ideas" (Topic: birth of the spectroscopy)

HOW TO READ THE HISTORY OF SCIENCE IN SCIENCE SCHOOL TEXTBOOKS FROM A SOCIOLOGICAL PERSPECTIVE: THEORETICAL AND METHODOLOGICAL CONSIDERATIONS INSPIRED BY THE IDEAS OF BRUNO LATOUR ABOUT NON-HUMANS AND NETWORKS

Abstract

We have carried out a historical research of chemistry school textbooks published in Spain in the course of the twentieth century. Based on our results we point out some theoretical and methodological considerations which are important to do a re-read of the way the history of science is commonly presented in school science textbooks. We propose to stress in two essential ideas of Bruno Latour's thought: 1) The role and agency of non-humans in the scientific knowledge and 2) An interpretation of history in science textbooks as a complex network, where there are not clearly-defined limits between history, philosophy and sociology of science and where history can be understood as a part of a "structure", which becomes more or less stable depending on the way as their "fibres" are "interwoven" in the narrative of science textbooks.

This is not a work on History of Science; this work is framed in one of the research lines between Science Education, the HPS approach. Researchers in HPS work on didactic reflection about the relevance of including contents of History and the Philosophy of science to improve learning and teaching science. The importance of the HPS approach in Science Education has been recognized by multiple authors attributing hundreds of arguments that justify their explicit inclusion not only in the curricular contents and classroom, but also in pre and in-service teacher programs. We have grouped those advantages in five categories, an extended frame of the three operational concepts for the west education in the proposal by Kieran Egan (Schulz, 2009):

Initially an intellectual dimension, which recognizes that science is historically and culturally dynamic, a cumulative body of knowledge that generates the techno-social company with an impact on societies and cultures. In the second instance we can recognize an individual contribution in which the HPS allows students and teachers to develop their potential as autonomous individuals including the culture of creativity and ability to think critically. A socioeconomic dimension where the HPS approach contributes in orienting education towards useful socio-economical and socio-political aims, acting on three levels: application, civic responsibility and democratic citizenship. A didactic dimension that can help improve learning science, and an affective dimension that personalizes, humanizes and demystifies scientists and scientific activity.

In practice these aims are translated to diverse actions that go from direct interventions in the classroom of which we can mention:

Historical episodes (AAAS, 1990; Klassen, 2009; Nersessian, 1995; Russ et al., 2009); historical anecdotes (Herron, 1977); discussions about historical explanations (Lochhead and Dufresne, 1989), discussions about the historical context of different discoveries (Arons, 1988), discussions about historical texts (Pessoa de Carvalho and Infantosi Vannucchi, 2000); staged historical episodes (Kipnis, 1998; Solomon, 1989); historical readings combined with experimental activities (Kipnis, 1998; Lin, 1998); historical reconstructions (Allchim, 2006; Izquierdo, Vallverdú, Quintanilla and Merino, 2006); historical cases (Bonini Viana and Alves Porto, 2001; Dawkins and Glatthorn, 1998; Elkana, 2000; Heilbron, 2002; Klassen, 2009; Kølsto, 2008); historical narratives (Clough, 1997, 2006; Conant, 1957; Irwin, 2000; Klopfer and Cooley, 1963; Matthews, 1994; Stinner, 1995; Stinner et al., 2003; Solomon et al., 1992); time lines (Metz et al., 2007); analytical reviews of researcher's original works (Jaffe, 1938; Klopfer, 1969); historical experiments (Ellis, 1989; Heering, 2009; Kipnis, 1996; Seroglou, Koumaras and Tselfes, 1998); historical vignetes (Roach and Wandersee, 1995); historical controversies (Kipnis, 2001; Madras, 1955; Niaz and Rodriguez, 2002); biographies (Izquierdo, 1996; Jaffe, 1938); historical models (Dolphin, 2009; Forge, 1979; Justi and Gilbert, 1999a, 1999b, 2000; Ryder and Leach, 2008; Stinner, et al., 2003); different activities using historical data or historical materials (De Berg, 2007; De Castro and Pessoa de Carvalho, 1995; Solbes and Traver, 2003).

In teacher formation programs, in curricular documents and textbooks. Indeed, these last ones are what we stressed in this work. Why do we focus our interest in them?

First of all, because there is a high dependency of teachers on textbooks for teaching history of science (McComas, Almazroa and Klough, 1998; Stinner, 1992; Wang and Schmidt, 2001), it has been explained by the lack of formal education that they receive in this field (Leite, 2002). Additionally, the type of historical material that is used is mainly what determines the image of science, of scientists and of scientific practice that is taught to the students, each history of science is teaching something on the nature of science (Allchim, 2004), and finally the fact that we have failed at persuading writers of textbooks about the relevance of the history of science (Heilbron, 2002), a situation complicated when analyzing the relentless demands of the market, characterized by the omission of these "decorative" subjects (Chang, 1999).

Moreover, various difficulties emerge alongside these facts, related to the historical contents themselves (scientific, historical and NOS inadequacy), the fact that the history present in textbooks obeys schemes of whig and internal history. In addition, scientists are mythicized, the historical reconstructions are armed in retrospective to satisfy the canons of positivism and the insistence of including the same "official" histories, the one of Lavoisier, Newton and Dalton, those of the 19th century school history (Kolsto, 2008), among others. This panorama has made investigators within Science Education ask continuously about it and to formulate many questions: How can the distorted presentation of the history of science in textbooks be corrected? (Brackenridge,1989) To whom should we appeal: the authors, publishing houses, the formation of more critical teachers, or to a deeper reconstruction of the same history and philosophy of science? (Smolicz y Nunan, 1975); How do we make school history of science the product of an interdisciplinary work in which scientists, philosophers, science educators and historians participate, and that serves the needs of science education? (Heilbron, 2002; Kubli, 2001) How do we resolve the tension between "historical truth" and "didactic utility"? (Kragh, 1992), and finally, should we give in to those who regard the advantages of the approach with scepticism and prefer not to include history of science in the science education?

We want to add an additional question to these: What has happened with the sociology of science in Science Education? To where and why has it been relegated? And What could its contribution be to our discipline in order to understand scientific knowledge in our present scene in which the borders between history, sociology and philosophy of sciences as disciplines become less and less rigid (Bloor, 1998)?. My doctoral thesis work is framed in these considerations and we propose two main research questions:

- Can we obtain a characterization of the contents of history and philosophy of science in science school textbooks published in Spain with a sociological perspective?
- Can we propose a new form of telling the history of science in science school textbooks from this sociological perspective?

In order to try and answer these questions, we are analyzing the contents of atomic theory, atomic structure and atomic models presented in Spanish science school textbooks from the secondary education level, published from 1860 to today. In our methodological and theoretical framework we use some ideas from a French sociologist: Bruno Latour. Latour (2001) conceives scientific activity as a complex network in which the connection between politicians, scientists, equipment, laboratories, non-humans, models and institutions, allows science to circulate. This circulation can be characterized in five knots:

- *Mobilization of the world*: How science objects, the non-humans, become mobile and move around the world.
- *Autonomization*: The way in which a discipline, a profession, a clique or a group of two colleagues becomes independent and forms its own criteria of evaluation and relevance.
- *Alliances*: How the scientist persuades and interests groups of people who did not have any interest in science before, and become involved in the history.
- *Public representation*: Refers to the massive socialization of novel objects and how the associations between people and non-humans are modified.
- And finally, the *Links*: The role of concepts and scientific ideas which hold many heterogeneous resources (from the other 4 nodes) together.

Somewhere in this network are the textbooks which can be considered like elements, widely connected and bound to the knot of public representation; but that we can also conceive in themselves as containers of many different networks. One of them is the history of science that they present, a network that we suppose can be characterized by the nodes proposed by Latour.

In order to establish if the history of the science contained in school science textbooks can be characterized as a network that allows us to characterize scientific activity, we used social network analysis in which the networks are made up of nodes and their relations. In the network analysis it is not the attributes of the nodes that are important, but how they are connected. In this way, for example, Rutherford and Bohr share various attributes –they both are European physicists, they are scientist who set forth a model for the atom– but this doesn't necessarily mean they belong in the same network, because there would have to be a relationship linking one to other, for example, that Bohr's main objective was to explain the instability of the Rutherford's model. That's the kind of criteria that we follow in our analysis. To represent the networks we use graph theory, and UCINET software.

In our analysis we have defined different categories that adjust to the five knots established by Latour (figure 1):

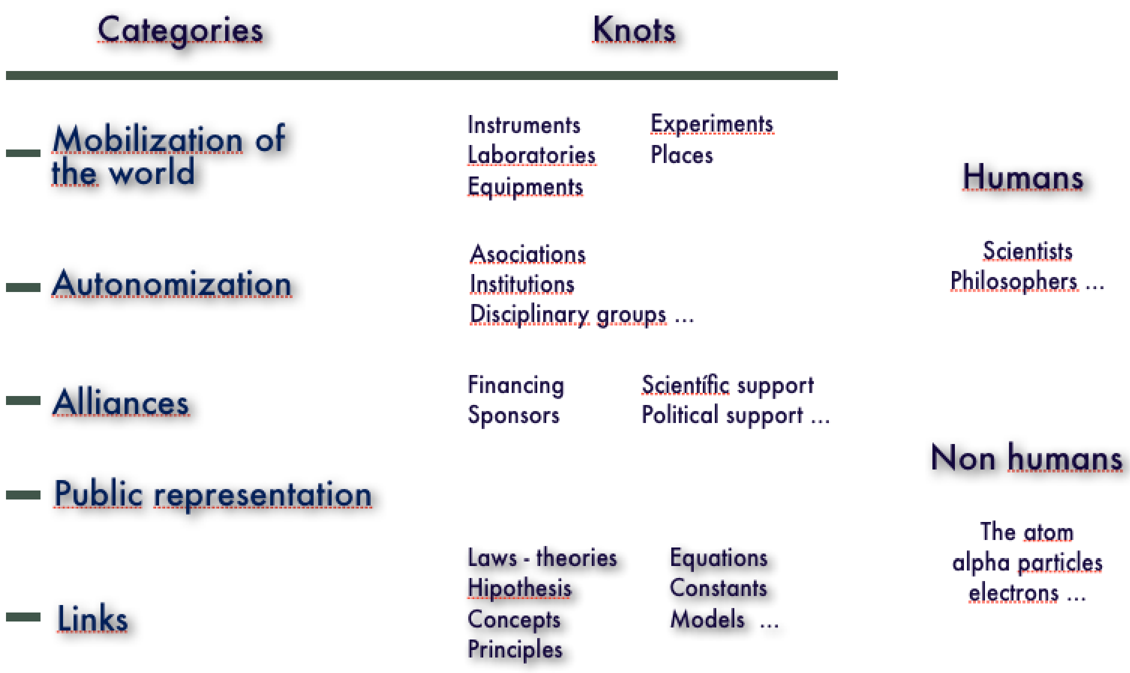

Fig. 1: Categories, knots, humans and non-humans define our networks.

When we represented these nodes and their relations we obtain more or less complex networks that tell us things about how these elements have been socialized in the historical narrative in the textbook. Thus it is possible to see how these different types of networks socialize some or other elements. Let's see some examples.

The first example is this book published in the 50's of last century (figure 2). Its network socializes only non-humans (the red nodes) and concepts (the green ones): we can talk about a "non-human" network. By chance, in this book there are neither dates, nor places either, it's a book without history of science. Figure 3 presents a network where few humans appear, the blue nodes, alongside them are the dates and the instruments. It's a little more complex network where the elements are more socialized. This book was also published in the 50's. The third book (figure 4) was published in the 40's which is the reason why we cannot make conclusions about a supposed relationship or dependency between the date of publication and the complexity or degree of socialization of the elements in the network. In this case in spite of having a network with less elements than the previous one, more things are socialized, here the places and the disciplinary groups appear, two important elements for circulating science.

Finally we have a book published in 1998 (figure 5), we could call it a contemporary textbook. In it socialization, connections, relations between non-humans and humans are widely overlapping. There are institutions, instruments, a congress, places, but first of all what stands out is the presence of experiments, the yellow nodes. These elements that Latour associates with the node of the mobilization are an important part of the historiographic narrative in this book and in others published after the mid 80's that we have already analyzed. Now we're working on trying to find when chemistry textbooks changed from prioritizing connections between non-humans and concepts to become books where the experiment is part of history, because the experiment is an important element which changes the way we can relate the history of science.

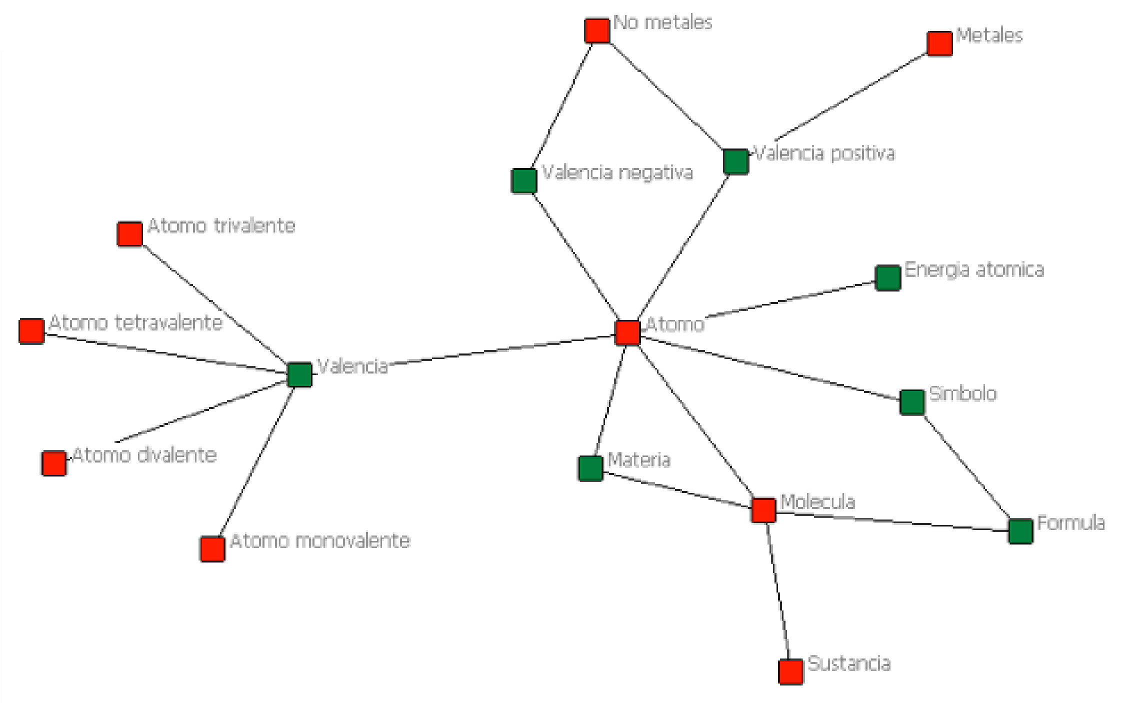

Fig. 2: An non-human network (Mendiola Ruiz, Jesús. *Física y química: Cuarto curso*. 195-. Editorial Cantabria).

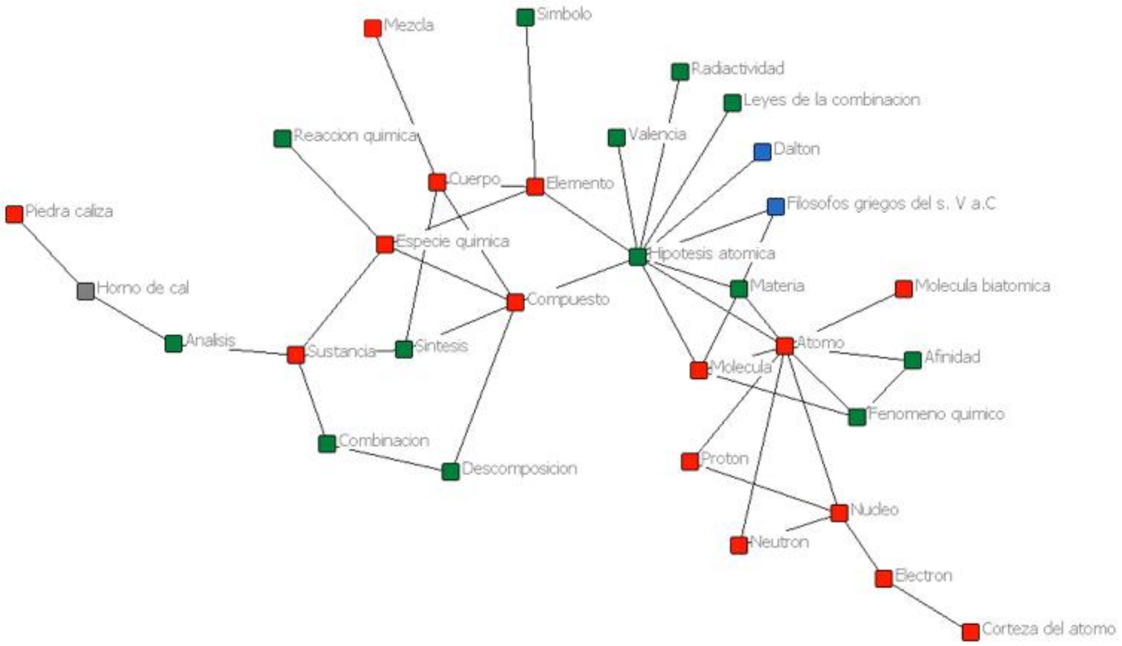

Fig. 3: Few humans appear. *Física y química: Cuarto curso de bachillerato* (Plan 1953). 1953. Ed. Bruño.

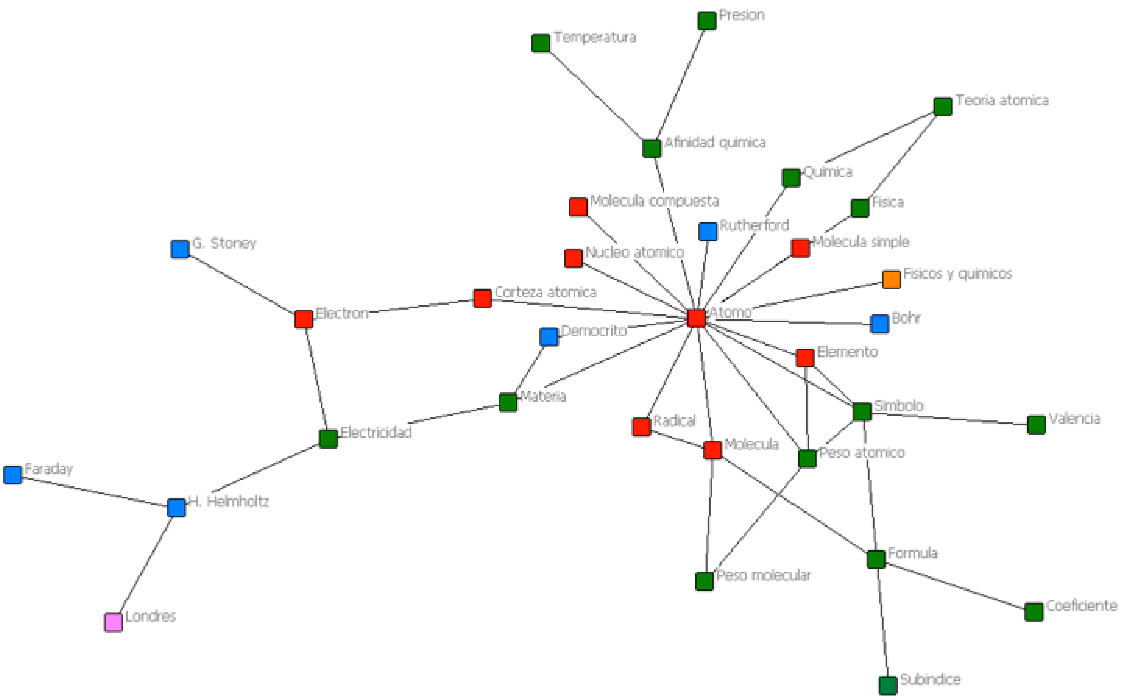

Fig. 4: A more socialized network (Moreno Alcañiz, Emilio. *Física y química: Cuarto curso*. 5th Ed. 1940. Editorial Heraldo de Aragón).

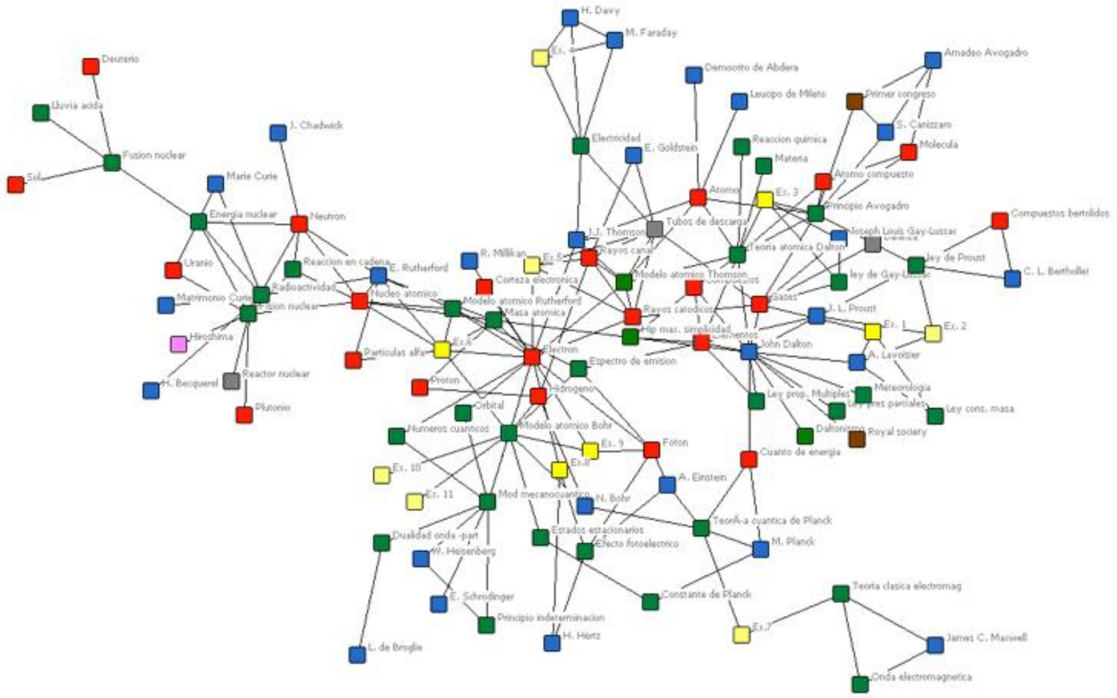

Fig. 5: A “contemporary” textbook network (García Pozo, Tomás; García-Serna Colomina Julio Rafael. *Química 1*. 1998. Edebé).

Until now we have analyzed 20 textbooks, but still there are many things that we have found when tracing the networks. Despite that, we can already see if there is a difference in the way the elements of the history of science that we have defined from our more sociological frame are socialized in the textbook. After every textbook is analyzed new questions rise, and we are working on them: Is a more socialized human/non-human textbook associated with a better HS? What happens with HS in textbooks where experiments appear as actors? What happens when the atomic models appear? Does changing to more “experimental” science textbook have any relation with changes in PS?

LABORATORY CULTURES IN EUROPE. THE 'GERMAN MODEL' IN THE EUROPEAN PERIPHERY

Geert VANPAEMEL
Hogeschool-Universiteit Brussel; Katholieke Universiteit Leuven, BELGIUM
Geert.Vanpaemel@wet.kuleuven.be

Abstract

In the last decades of the nineteenth century, many European countries adopted a laboratory science system, in which the German model served as the prime example to be imitated. This is often taken as proof of the central role accorded to German science, and positions followers of the German model on the periphery. In this paper another interpretation of this diffusion process is proposed, stressing the complementary nature of centre and periphery. The centre embodies the shared values of the wider community and serves to connect various members of that community. The centre only emerges as such as a focal point for aspirations fostered at the periphery. The diverging and often contrasting interpretations of the German model of laboratory science exemplify this complex and ambivalent relation between centre and periphery.

In the introduction to *L'Europe des sciences. Constitution d'un espace scientifique* (2001), the editors Michel Blay and Efthymios Nicolaïdis explain how it was their intention to make a study of the influence of scientific knowledge on the homogenization of societies. They believe that European science as such constitutes not only a geographical category, but also an "intellectual unity": the particular knowledge created in Greek Antiquity was transformed in Europe during the Scientific Revolution, and subsequently exported towards other regions of the world. In particular for Europe, travels, translations and centre-periphery relations have all contributed to the unification of a single scientific space.[1] But the existence or rather the creation of a unified space raises many questions. How can distant participants of a scientific community interact with each other over long distances? How do shared values arise from different local traditions? How is a 'homogenized' science constructed, received and appropriated by scientists in various contexts, and how is scientific knowledge itself affected by the processes of diffusion and adaptation?

Sociologists have used for a long time the concept of a unified world-science system. Following Braudel and Wallerstein, an understanding has grown of the characteristics of global science, its hierarchical structure and its homogeneity, but also its differentiation and segmentation. World-science is often considered merely an extension of the structural features of the local scientific community, where scientists share their ideas in exchange for recognition and

[1] Michel Blay and Efthymios Nicolaïdis (eds.), *L'Europe des sciences. Constitution d'un espace scientifique* (Paris, Editions du Seuil: 2001), "Introduction", p. 9-11.

emulation.[2] But in as much as there exists a unified scientific space, there are different levels of integration which cannot be ignored. Every scientist is part of individual, national and international communal formations, which have different ways of operating. The integration of these communal formations may depend on political, ideological or economic factors, which may destabilize the global system and lead to the decommunalization of world science.[3]

What can be deduced from these studies, is that the existence of a unified space necessarily presupposes the existence of a centre. In the centre, the values of the epistemological space are articulated and embodied. It is not necessarily linked to a geographical location. Rather, the centre is, according to Edward Shils, the representation of the order of symbols, of values and beliefs, which govern the community.[4] As such, the centre is a powerful actor that holds a community together. The centre is closely related to the notion of 'elites', and attains a formal status by virtue of institutionalization. The periphery, on the other hand, is characterized by exclusion and distance from the centre. The views of Shils were further developed with respect to the international scientific community by Rainald von Gizycki in 1973. Basing his ideas on a comparative study of nineteenth century science in Germany, France and Great Britain, Gizycki defined the centre "by the fact that works produced there command more attention and acknowledgement than works produced elsewhere. […] the theories and observations produced there become sources of influence and objects of emulation."[5] There may be different centres for different scientific disciplines, but there is a tendency for the centres to be clustered. At the same time, there is a tendency for centres to be displaced by new, emerging centres.

Gizycki's view on scientific centres is based on competition, a race for scientific leadership. Research located at the centre of the scientific community is in all respects superior to research in peripheral regions. Countries in the periphery are countries which have lost the race, albeit only temporarily. The periphery inevitably attempts to imitate the centre or to modify its own structures to bring them closer to the models drawn from the centre. Gizycki observes:

> "A scientist who wishes to make an important contribution to science and thus to 'make his mark', must, if he lives and works at the periphery, conform with the standards embodied and espoused by the centre. Het must know the substance of the centre's accomplishments by reading its scientific literature; he must know the language of the centre. He is forced to live in its shadow."[6]

In this model, the only activities granted to the periphery are imitation, adaptation and emulation of the centre. In essence, the periphery is mostly unproductive of knowledge and a passive, perhaps even a superfluous bystander of the scientific community. To understand the scientific community and the history of scientific developments, it is sufficient to look at the centre.

Recent studies have presented alternatives to this model. In global studies, students of 'non-Western science' have questioned the putative unity of science and its central values. As Kapil Raj noted: "In place of a unique 'modern science', it is now accepted that there are many national and local knowledge traditions and dynamics spread across most of North and West Europe, with diverse, and at times contradictory, intellectual agendas and influences throughout the early-modern and modern periods."[7] The unidirectional spread of Western Science, as modelled in the 60s by George Basalla,[8] was not a simple emanation from a pre-existing centre, but the result of complex process of conflict, acculturation, and appropriation. Marcos Cueto has equally rejected the traditional notion of periphery as being unhelpful in understanding the dynamics of a 'peripheral' region's scientific development.[9] In Europe, the community of scholars constituting the STEP group has equally questioned the notion of periphery. In a joint paper, Kostas Gavroglu and others have pictured the periphery as an active receiver, making "a shift from the point of view of *what has been transmitted to the view of how, what was received has been appropriated*."[10]

To many scholars the dichotomy between centre and periphery should probably be left as a descriptive category to researchers of the present day world science system, but without further historical or explanatory value. Yet, I argue that the centre-periphery dichotomy can be fruitful if the perspective is shifted from a competitive model towards a complementarity model. In this model, a centre is not simply a place where knowledge is produced and standards are defined, but a place to which, by actors at the periphery, certain meanings and values are attributed. The centre is not the origin of the space around it, but it is created by the projection of local ideologies on a symbolic object. This presupposes a two way mechanism of appreciation and emulation between centre and periphery, in which both have important roles to play. Centre and periphery participate as complementary forces in the production of shared community values. The very use of the centre and periphery vocabulary may help to understand how a common identity within the community is being created and shared.

Much of the scholarly literature focuses either on the characteristics of the centre, or on the development of the peripheral region. The actual relation between centre and periphery has been taken for granted as if it seems to follow immediately from their respective positions. In this paper I consider the centre and periphery to be mutually dependent on each other. The centre emerges when it is recognized as such by members of the community, whereas by this very act these members show themselves to adhere to commonly shared values and to be an integral part of the larger community. I maintain that the centre-periphery model should not be used to make a distinction between two geographical or cultural spaces, but rather that it can help to underscore their connection. A close analysis of the centre-periphery metaphor, used by different actors in different locations and from different perspectives, may show how values and practices are perceived and interpreted.

One example of a typical centre-periphery narrative is the creation of modern laboratories at the end of the nineteenth century. In many countries, this laboratory movement was supported by reference to the lead taken by Germany in science and industry. But the role model of Germany in this process as interpreted according to the simple competition model of Gyzicky cannot explain a series of complex and ambiguous problems. There is no exact definition of what the German model was. In fact, many nineteenth century observers stressed contrary features of this model, in order to advance their own agendas. Also, no single country in fact copied the German model, but produced a locally adapted form of a laboratory system. What was common, however, was the agreement between many scientists and politicians, that if a model existed, it had to be found in Germany. That this 'German model' was in fact a construct adapted to local needs, shows how the relations between centre and periphery should be reconsidered.[11]

Laboratory Cultures and the German Model

During the second half the nineteenth century, the modern laboratory emerged as a new, important institution of science. Laboratories had existed before, and were recognized as privileged spaces for experimental work, in particular in chemistry.[12] But the new laboratories of the nineteenth century were different in scope and institutional status. In universities large laboratories were built for pedagogical reasons, instructing students in routine scientific manipulations, while providing some space for more advanced research. Somewhat later, laboratories were set up for agricultural and industrial research, transforming the nature of technical research and invention. More generally, the laboratory became an abstract institutional category of scientific practice, unconnected to a certain location or researcher, and very often referred to in the plural. This institutional role of the laboratories inspired Pasteur to describe them as "temples of the future, wealth and well-being".[13]

The building of laboratories was typical of the modernization era of science (1850-1950), when laboratories were considered a first and necessary step towards the implementation of scientific practices within a national culture. In university education, the laboratory underscored the rise of pure science as a basic element of intellectual culture. In government policies the evolution towards a modern, enlightened state was translated in the creation of experimental agricultural stations, food analysis laboratories and bacteriological institutes. Laboratories thus transformed many aspects of intellectual life, industrial activities and medical practices.

One of the characteristics of these laboratories was their uniformity to an international standard. This uniformity warranted access to the international scientific community and became a recognizable feature of modernization. Very often, the so-called 'German model', based on both the academic laboratories in German universities as well as on the industrial

[11] We restrict our research to European countries, where the use of the term 'periphery' refers to a different situation compared to the periphery on a global scale. Whereas European countries always felt related to the European centres, colonial and postcolonial experienced a much sharper difference with Western countries, both in size of the scientific community as in the cultural distance purposely maintained by colonial powers. Also, for briefness, I will not discuss the development of the laboratory system in Germany and the internal response to the (externally constructed) German model.

[12] Maurice Crosland, "Early Laboratories c.1600-c.1800 and the Location of Experimental Science," *Annals of Science* 62 (2005) 2, p. 233-253.

[13] Quoted in René Vallery-Radot, *La vie de Pasteur*, (Paris, 1900) p. 215.

laboratories in the German dye stuff industries, was put forward as the ideal model to replicate. In particular in peripheral countries, adaptation of this German model was a strong rhetoric for underscoring the quality of their own scientific culture.

The role of the German model in the reform of universities and the creation of laboratory facilities has been amply studied in the cases of France and England.[14] Competition between nations was a driving force in these debates, with Germany clearly considered in the lead, but the outcome was as much determined by domestic issues as it was by simple imitation of a scientific centre. As George Weisz observed on the French debates: "It is impossible to cite more than a few concrete instances of institutional imitation. […] A highly idealized image of German universities served to symbolize a variety of goals and aspirations. The most contradictory positions were defended by appeals to the German example."[15] And with respect to England, George Haines wrote: "To claim in each instance [of newly founded English colleges] direct German influence would be preposterous. But the widely and continuously cited German example, the intensively fostered fear of German industrial competition, and the German experience of many of the leading teachers played important roles in providing an impulse, otherwise so long delayed as to be almost inexplicable."[16]

The cases of France and Germany demonstrate already how the 'German model' was a malleable concept which could be used for almost any purpose. In many instances, the laboratories and universities of Germany were only described in abstract generalization, and different aspects of the German system (support by the State, laboratory research as part of university education, emphasis on direct links with technology) were variously given as fundamental features. The German inspiration of reformers was in any case more important than any German example to be copied or imitated.

Apart from these core countries, there are only a few studies on peripheral countries. References to the German model are not absent, but almost never critically analyzed.[17] The very definition of what the German model represented could vary widely. The target audiences may have been different, as also the outcome of the reform. Involvement of government institutions and the interest of local industries may have changed the message of reform substantially. The connection to agriculture, health policy or industrial development must certainly have added a variety of local flavour. We have, as yet, no overall understanding of how the German model was actually defined, used and implemented in most European countries. But from what can be gathered from exploratory readings, some themes for further research readily emerge.

1. At what time, and through which channels, did the German model actually find its way into 'peripheral' debates?

In most countries the apostles of the German model had studied for some time in Germany or were personally acquainted with German scientists. In other cases, German scientists settled in peripheral countries. In any way, the influence of German science is clear, but to go from personal experiences to a general 'German model' presupposes a creative step in defining what the German model was about.

The conscious use of the 'German model' appears to have come into use only in the 1860's. As yet, I have not found any use of the German model in 'peripheral' countries, before it became in vogue in France and England. This may indicate that these countries were actually instrumental in promoting Germany as the leading country in science. One suggestive example can be found with the Portuguese physiologist Costa Simões who in 1865 visited universities in Germany (Bonn, Würzburg, Heidelberg, Munich, Göttingen and Berlin), France (Paris), Belgium (Brussels, Leuven, Ghent and Liege), Holland (Amsterdam, Leyden and Utrecht) and Switzerland (Zurich). He decided to organize his own laboratory in Coimbra on the example of the Berlin University, but he did so after receiving advice from different experts. The status of German physiology was a topic of conversation between many colleagues, not only German. The instruments he acquired for his laboratory were bought in several locations (Paris, Berlin, Liege and Vienna), which may indicate that his actual implementation of the Berlin example was broader than a simple imitation and in some cases was only indirectly linked to the German sources.[18]

[17] E.g. for Italy, the German model has been studied in relation to the creation of a scientific community. See G. Pancaldi, "The German model and the origins of the Italian *Riunioni degli scienziati*", in Dietrich v. Engelhardt (ed.), *Zwei Jahrhunderte Wissenschaft und Forschung in Deutschland. Entwicklungen – Perspektiven* (Stuttgart: Wissenschaftliche Verlagsgesellschaft mbH, 1998), pp. 171-178; Maria Pia Casalena, "The congresses of Italian scientists between Europe and the Risorgimento (1839-75)", *Journal of Modern Italian Studies* 12 (2007) p. 153-188.

[18] Maria Burguete, "Laboratories at the Faculty of Medicine of the University of Coimbra in the XIX century," *Scientific Research and Essays,* 5 (2010), p. 1402-1417.

Likewise, the Lisbon physician Marck Athias became aware of the debate on German science during his studies at the Faculty of Medicine in Paris in the closing years of the nineteenth century. Athias never studied in Germany. His French background was apparent in his ten year career at the Pasteur Institute in Lisbon. As head of the Lisbon Institute of Physiology his work was characterized by the positivist ethos of French science, although his scientific practices was modelled on the German tradition.[19]

Even when personal acquaintance with German science was available, the outcome was not necessarily only directed towards Germany. Early physiologists such as the Russian Ivan Mikhailovich Sechenov studied with a.o. Carl Ludwig in Vienna, Emil Du Bois-Reymond in Berlin and Claude Bernard in Paris. Although he used Du Bois-Reymond's experimental apparatus in his own laboratory, his work bears the influence of all the great physiologists he worked with.[20] Finally, the Cracow physics professor Zygmunt Wroblewski had studied in Berlin, Heidelberg and Munich but consequently made an extensive tour of other European research institutes, ending up in Paris. When he set up his laboratory at Cracow, he brought the needed apparatus from France.[21] If the German model was a powerful rhetorical device, it cannot be assumed to be an actual well-defined model to be copied.

2. Which values were associated with the articulation of the German model?

What was the rhetorical power of the German model? Was it based on an objective evaluation of scientific output? Some examples suggest that admiration for German science was often part of a larger cluster of values. Germany was heralded for its artistic and literary culture, its national vigour (in particular after the unification of the German states in the 1860's), its industrial successes, the honours bestowed on science by State and the general public, its victorious clash with France, etc. It has been suggested by Andrée Despy-Meyer and Didier Devriese in their study of the Belgian physiologist Paul Heger and his collaboration with Ernest Solvay to create new research laboratories, that the enthusiasm for German imperial science among progressive liberals should be understood by the obvious appeal of the anti-clerical politics of Bismarck, whereas the admiration from French positivism had been erased by Germany's *Kulturkampf*.[22] On the other hand, in France, German science was sometimes associated with a medieval world view and under the influence of religion.[23] In the Habsburg Empire many German speaking scientists integrated themselves in the German scientific community, in the hope of contributing to some ethnic German community, but non-German speaking scientists only grudgingly accepted the domination of German inspired institutes. In Prague the university obtained the liberty to teach in Czech language, as Cracow did in Polish.[24]

These examples suggest that the positive mention of a German model should always be interpreted against a much larger field of values associated with the German state and German culture. It becomes important therefore to carefully position the advocates of the German model in the social, cultural and political spheres of their country. Possibly, the values associated with the German model connected to the cultural ideals of existing or upcoming elites. For France and England, it has been established that the outcome of the 'German reforms' supported the rising social status of bourgeois intellectuals. For peripheral countries in particular, the relationship of 'German-minded' scientists with social elites and public authorities has to be looked into. In particular in agriculture local circumstances and ownership of the land had great impact on the implementation of agricultural stations and laboratories. Russian agricultural stations grew from laboratories on private lands, then developed into regionally based *zemstva* stations and finally to state bureaus.[25] Possibly the involvement of the Russian state in the promotion of the French Pasteur institutes was more effective than the abstract rhetoric of the German model.[26]

3. How did the German model transform the national science system?

The science system comprises all cognitive and institutional resources available to a country for its industrial and cultural development. Universities, research institutes, scientists, government agencies and industrial actors all contribute to produce knowledge and wealth. At the same time, the system itself is a distributor of values: it conveys status on important

actors and authority on institutions, legitimating scientific practices while undermining rivalling traditions. The import of a new model inevitably disturbs the existing science system, bringing new actors to the front and displacing other from their positions. The introduction of the German model, with its emphasis on the building of large laboratory facilities, caused increased tension with traditional forms of knowledge such as embodied in scientific societies or non-laboratory based disciplines. When in Belgium the large laboratories were built in the final decades of the nineteenth century, it put the power of scientific research in the universities, while the Royal Academy of Science lost much of its influence in Belgian scientific life. The introduction of agricultural stations replaced traditional agricultural practices. Louis Ferleger has argued that the success of the German agricultural stations actually caused a setback of agricultural efficiency in most North Sea countries where the German stations were admired and copied. Those countries neglected to provide enough funding for sustained agricultural research and relied too much on German knowledge, which was not adapted to their local needs.[27] Similar evolutions can be seen in the introduction of bacteriological laboratories, replacing the expertise of hygienists. Last but not least, the German model interfered with the balance between pure and applied research. Introducing laboratories in engineering education sometimes served to make the engineer appear more scientific, thus increasing the social distance with lower technical personnel. Similarly, the large laboratories available to university researchers emphasized the difference between professional researchers and amateurs.

Conclusion

The unified space of European science arguably emerged with the general enthusiasm, spread throughout European countries, for the German model. The German model, however, was not a static, well defined system which other countries envied and were ready to copy. Rather, the very definition of the German model, the values associated with it and the actual consequences of the adoption of the model varied largely among European countries. A better way to understand the international appeal of the German model, may be to look at it from the complementarity model of centre and periphery. The German science system, as conceptualized by numerous authors throughout Europe, embodied the central values of modern science and was thus a crucial binding element to bring different scientific traditions together within one community. Importantly, the label 'periphery' which suggests itself in studying the spread of the German model, should to be seen as an intentional localization of European countries around the centre. The 'adoption' of the German model, instead of being a mark of emulation of the centre by the periphery, can be understood to emphasize the modernity of the adopting country, its very nearness to the centre, and its acceptance of the central values of modern science.

CENTRES AND PERIPHERIES IN EUROPE: THE CASE OF GREGOR MENDEL'S DISCOVERY[1]

Jiří SEKERÁK
Mendelianum Musei Moraviae, Brno, CZECH REPUBLIC
genetika@mzm.cz

Abstract

Mendel's elucidation of hereditary processes based on his experimental model with plant hybrids in 1865 was a solely standing achievement in the 19th century biological science. The biologists were working within the mainstream of science influenced by Charles Darwin who brought the up to then hereditary research into the context of heredity of acquired characters. From this viewpoint Mendel was solving a question that was not considered as problematic in the nineteen-sixties. Mendel worked in the Brno Economy and Agriculture Society intended for practical exploitation of knowledge in the improvement of sheep and plants to contribute to the industrialization of the Habsburg Austrian Moravia following the British progressive model of society drawing wealth from the industry production. Brno was a suburb of Vienna in Mendel's days focusing its attention at founding a university and technically oriented school of higher learning. Open scientific societies implemented the experimental method and cultivated science as a mighty instrument in achieving societal welfare. Many an Austrian dissident scientist found a refuge in Brno that attracted motivated people to engage in the starting industry, business, banking and education. On the other hand the documents testify that Mendel was a loyal teacher implementing the school reform of the establishment enthusiastically. Mendel in his experiments did the artificial pollination alone. As a son of a peasant he did most of the 'dirty' gardening work alone. Not using white gloves in performing artificial pollination Mendel was a man at the fringe of the academic style. The shift took 35 years. In 1900 Mendel's discovery became the fundament of a new science –genetics– making revolution in the study of life systems.

Periphery of time

Mendel's work on the experiments with plant hybrids has been considered a most significant document in the history of the ascent of human thought in general, and in the history of science in particular. Although the substance of Mendel's paper fell into oblivion for 35 years. The question is, why? It was published in two lectures on serialization in 1865 in the meetings of a local Nature Research Society and published in the fourth volume of the Society's journal.[2] The first page of

Mendel's manuscript has been known to many, but few know that the note in the upper left hand corner says in German '40 reprints' and its author is Gustav Niessl, a botanist and secretary of the Nature Research Society. It was Niessl who persuaded Mendel to publish his lecture that otherwise would never be printed. Moreover, shortly after 1900, when scientists regretted that Mendel's paper remained unnoticed so long, Niessl gave a heavy argument that Mendel's discovery paper had not been unnoticed, but was intentionally neglected.

Mendel's discovery was pushed to the periphery of scientific interest because it did not comply with the then biological knowledge. In 1904 Niessl reported that Mendel's discovery work was well known but was neglected because significance was attached to the ideas of Darwinism. In those days Mendel's concept seemed to contribute little to Darwinian studies in spite of the fact that in the first pages of his paper Mendel stated clearly that his work was significant for the solution of the question of the development of living forms.[3]

Periphery of specialization

Mendel's paper on plant hybrids had no special value for the then botany because its results attracted no attention. It became known to a few hybridizers working in the field of the origin of new forms. But the progeny of Mendel's hybrids reverted to the old parental forms according to the famous segregation ratio 1:2:1. Thus his scientific conclusions were implausible for the then evolutionary studies. Even though his experimental achievement was known, it was overlooked.[4]

Mendel complained to professor Naegeli of Munich University that nobody found interest to repeat his experiments.[5] Mendel was of the opinion that it was due to the absence of verification of his experimental data caused by the Bruchus pisi disease that devastated the pea breeding in the Brno region in those years. Mendel did not realize that the main obstacle of the reception of his paper laid in the incompatibility of his language as a physicist (speaking of 'genotypes') with the mainstream science botany that was concerned with 'phenotypes'. Mendel's concept of invisible elements that he grasped by means of mathematical statistics and theory of probability could not appeal to any botanist of his day.

Invisible elements

In his days Mendel had no possibility to reach the elementary structures and their function in the process of inheritance. Mendel was facing a typical problem of the so-called black box formulated one hundred years later by Norbert Wiener, the founder of cybernetics.[6] Plainly saying if we study a hidden mechanism, a black box, into which we cannot look into, there is only one possibility how to construct an idea about its functioning with help of given principles, e. g. Occam's razor. The construct comes from one's control of inputs and outputs into the black box and out of it. Comparing their mutual interactions one can trace their mutual dependence on each other. Respecting the basic methodological principles (causality, dynamics, Occam's razor etc.) one can construct a quite exact model of the hidden mechanism in action.[7]

In experimental conditions such an approach is possible only when **the initial conditions** of each experiment are given exactly to enable a precise comparison with the results. Mendel is the only experimenter of his time who specified clearly the initial conditions before opening his hybridizing experiments. Hybridizing experiments whose results could not be compared with the exactly defined initial conditions (inputs) were worthless, i.e. they could not lead to discovery of the hidden mechanism of inheritance within the black box.

Thus Mendel did not verify the concept of heredity by means of blending characters of organisms. Mendel offered a model of transfer of genetic information instead. Mendel's concept of inheritance is an information process in fact which is testified by his definition of the essence of the element in his Concluding Remarks:

> "This development proceeds in accord with a constant law based on the material composition (*materielle Beschaffenheit*) and arrangement of the elements (*Anordnung der Elemente*) that attained a viable union in the cell."[8]

[8] See ref. 1, p. 42.

Quite intentionally Mendel stressed **the arrangement** of elements. Information in the present-day-thinking is the arrangement of elements (*in-formation*) in the material carrier.[9]

Periphery of place

Brno of Mendel's days was a provincial town and centre of Moravia. In the Austrian monarchy it played the role of Austrian Manchester. Its many textile factories chimney stalks filled the horizon of Brno competing in number with the monastic and church spires so typical for Habsburg sphere of influence. The dynamic industry in Brno attracted many entrepreneurs from various parts of Europe. The Brno melting pot became the refuge of many a nonconforming scientist of the Habsburg Empire.[10] The Economy and Agriculture Society in Brno initiated foundation of new modern schools that taught 'real' subjects such as natural science, accounting, engineering, book-keeping, architecture etc. The new educational trend needed an appropriate educational staff and Mendel seemed to be in the right time in the right place. Majoring in physics, he minored in natural science and was an extraordinary qualified help to the headmaster in fulfilling the official task to produce well trained students capable of industrializing the country.[11]

In the fifties of the 19th century Brno started a school reform forging a new way to the technically oriented education. New middle and high schools were established balancing the real subjects with the old concept of humanities. The documents testify that Mendel was a loyal teacher implementing the school reform of the establishment enthusiastically.[12] Next to middle and high schools institutes of higher leaning were founded to generate a new élite of businessmen, bankers, export/import experts and a highly motivated class of chemists, engineers, architects, economists, accountants, transporters, road and railway builders, sellers of various goods, customers and improvers of all sorts. In the fifties of the 19th century first gas lamps were lit in public places in Brno.

Research into nature specialized in looking for natural resources, growth of the effectivity of fodder plants and animal improvement. The demand for teachers in real subject was extremely high. Mendel head lessons on physics and natural science in Vienna from 1851-3 and was immediately offered a place of a substitute professor both at the high technical school and the technical institute of higher learning. In 1854 he became a member of the Economy Society that was a sort of the regional academy controlling industrialization, education and societal welfare in Moravia. Mendel's colleagues in the Economy Society appreciated 'Mendel's époque making experiments' in plant hybrids because the solution of that problem was crucial in their effort to achieve new colour varieties of ornamental plants. Nobody else considered Mendel's findings significant in spite of the fact that the Nature Research Society's mailing list comprised more than 130 names of institutions and scientists of European reputation and even overseas addresses to whom Mendel's paper was sent.[13]

Periphery of style

Mendel's detailed experiment was a result of the overlapping of physics and botany. Overlapping as a phenomenon is extremely improbable to occur in the centre. This style of Mendel was unique and unparalleled before. What was the difference between a botanist hybridizer and a physicist performing a hybridizing experiment in plants? Mendel gave precise initial conditions of his experiment that a botanist does not. To extend precision of the initial experimental parameters, Mendel worked for two years testing the plants on stability of characters, to prove their constancy in as many succeeding generations as possible. Even today such minute characteristics would appeal to a geneticist, not a botanist. Even some of those conventional evolutionists neglected the significance of genetics.[14]

From the periphery to the centre

We can assume that genetics could originate without Mendel as well. The expansion of science reached a certain point around 1900 and what came was a sort of crisis of a traditional Darwinist concept. New ways of answering questions are discovered and Mendel belongs to them. It means that they discover someone who has coped with those facts better than they did. They felt his authority and relied on Mendel, that's why the classical era of genetics is called Mendelism.

Mendel (1822-1884) did not live to see the acknowledgement of his theory of inheritance.

In the 20th century, after the so called "rediscovery" by Correns, De Vries and von Tschermak, Mendel's model of the transfer of hereditary elements or genetic information from generation to generation was often interpreted in different even contradictory ways. In Mendel's days (or more exactly in Mendel's obituary in a newspaper) only the members of the Brno Section for Pomiculture, Viniculture and Horticulture in the Economy Society appreciated Mendel's hybridizing experiments as marking a new époque.

For centuries the role of the environment in hereditary processes was considered decisive for evolution. Mendel's theory of (on) stability was long misunderstood as contradictory to change. Mendel explained the process of change as rooted in the ways of organization and reorganization of hereditary elements. It took rather a long time to establish complementarity of Darwin's question 'what changes' and Mendel's answer 'what persists'.[15] Prior to establishing integrity of heredity with evolutionary views, fierce debates on the relationship between Mendelism and the inheritance of acquired characters. The geneticists opposed the inheritance of acquired characters. This debate seemed to seize after the Great Evolutionary Synthesis in the USA in the thirties of the 20th century.[16] This process culminated in this: how can we satisfactorily answer the question posed by R.A. Fisher: *What did Mendel actually discover and what did he think he discovered?*[17]

STUDIES OF MEDICINE FROM THE GENDER PERSPECTIVE

Maria BURGUETE
Instituto Investigação Científica Bento da Rocha Cabral, Lisbon, PORTUGAL
mariaburguete@gmail.com

Abstract:

The beginning of natural sciences came to predominate in medicine with the emergence of natural scientific thinking in the first half of the 19th century. A great deal of physiological progress in the 19th century was centered in Germany, where apparatus developed by physicists were judiciously used in physiological experiences. This trend is clearly illustrated in my previous article (Burguete, 2010).
Therefore, the creation of the Laboratories of Experimental Physiology, Histology, Toxicology and Pathological Anatomy was the result of the reorganization of the Medicine Faculty at Coimbra University in 1866-1872, according to the model of the Berlin School of Medicine.
In the sequence of this transition comes the initiation of experimental work providing better conditions for the learning process of medical sciences for the Coimbra faculty of Medicine. As the public understanding of science as well as scientific literacy became accessible to a wider public (women included), a kind of a revolution from the gender perspective naturally takes place in the world of knowledge, not only in Portugal but also in Germany and all around Europe. I will present only two cases studies: Portuguese and German.

Introduction

Why Science & Gender? This is a controversial topic and at a first glance we can look over the positions and works of women researchers from different scientific areas and visualize the frontiers they had to overcome just because they were women doing science. We need to correlate gender questions with science questions and this task is a very difficult one.

Ruth Hubbard, a great scientist from Harvard University, where she had worked side by side with her husband, George Wald (Nobel prize in Medicine or Physiology,1967), only after her 50th birthday did she realize the influence of extrinsic factors (*society*, *behaviour* and *mentality*) upon intrinsic rationality of science while producing science itself. She says that*, "such as writers, all that scientists can do is to tell stories and just like in literature, those stories should be based upon political and social reality from actuality."*

So, let us tell a story about two women, both living under the influence of a monarchic political system and belonging to a similar social reality:

- **Domitilia Miranda de Carvalho (1871-1866)** – Portugal.
- **Rachel Hirsch (1870-1953)** – Germany.

Curiously, what happened with Domitilia Miranda de Carvalho (fig. 2) in the 19th century concerning the way she had to dress herself still happens today in a more sophisticated way, but the reaction still exists from the world of men when a woman does not follow a pattern previously approved by men, the so-called intrinsic rationality…

False paradigms pretended to support unquestionable questions in medicine and behavioural sciences to push women aside. In spite of women having been admitted at European and American universities one century ago, in 1950 we could still hear conversations with sentences like this:

> ”it was not worthy for women to submit as a candidate for *professor of biochemistry*!”

This is unbelievable in the 20th century!

Development

In the first half of the 19th century, natural scientific thinking came to predominate in medicine - The Dawn of the Natural Scientific Era (Burguete, M. 2010).

Philosophical approaches became less relevant and research concentrated on the biological, physiological and chemical foundations of life.

Finally, in the 2nd half of the 19th century, women could already complete university studies in many countries such as Portugal and Germany.

In this work we have two case studies where the stories of the very first women to be medical doctors in Germany – **Rachel Hirsch (1870-1953)**– and Portugal –**Domitilia Miranda de Carvalho (1871- 1966)**– are presented.

Portuguese Case Study: the First Medical Doctor Woman

For the first time in 1894, a woman, Domitilia Miranda de Carvalho, was accepted at Coimbra University (fig. 1) to study Mathematics and Philosophy under one condition:

> “By expressed decision of the Rector, she would have to dress discretely and always in black with a black hat also discrete, in order not to disturb her masculine colleagues, also obliged to wear black clothes.”

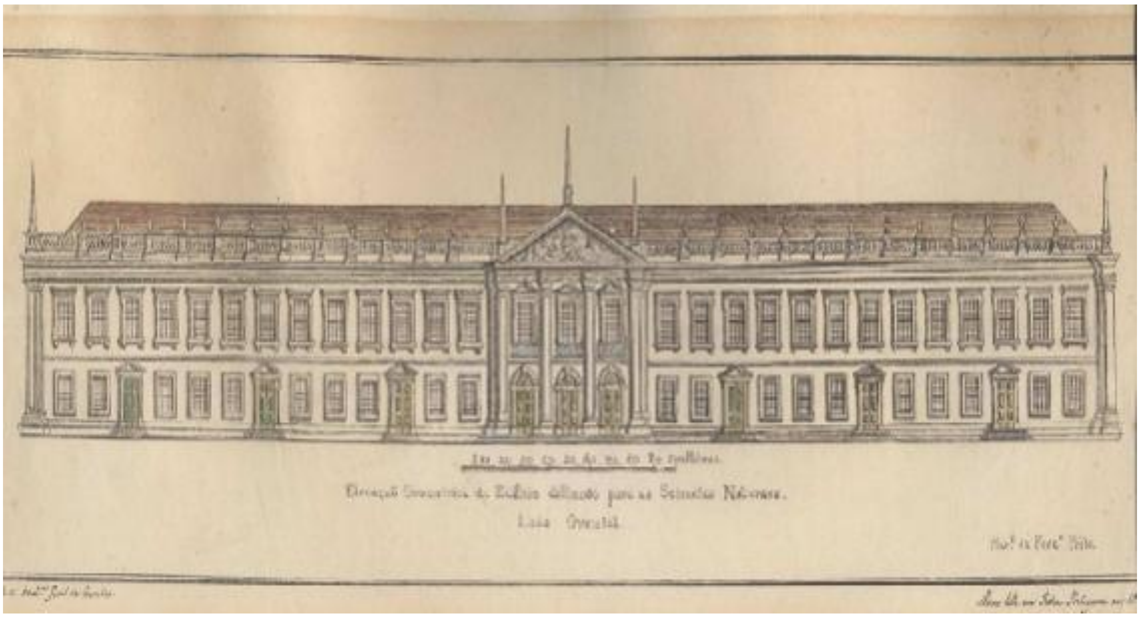

Fig. 1: Faculty of Medicine of Coimbra University in the 19th century.

Why the imposition of such conditions? Because many professors and male students agreed: women did not belong at university!

After the conclusion of Mathematic and Philosophy courses in 1894 and 1895 respectively, she wanted to study Medicine. However, women who wanted to become physicians had a particularly difficult position: the male leaders feared competition and publicly discussed the "naturally feeling of shame of women" or even "the physiological idiocy of women".

Fortunately, she was a monarchist and also a great friend to Queen Amélia de Orleães (fig. 3), the last Queen of Portugal, who supported all costs and expenses, therefore creating all the needed conditions in order to be able to finish her medical course in 1904 with 16, an excellent result. Therefore, she was the very first medical doctor woman in Portugal.

Fig. 2: Domitilia Miranda de Carvalho.

Fig. 3: Queen Amélia (1865-1951) married King Carlos (king of Portugal). With the age of 24 she was Queen of Portugal.

Afterwards she proceeds with her professional life as clinical doctor in Lisbon and at the public hospital. Later on she accepted a place as a teacher of the first secondary school – *Liceu D. Maria Pia* – created only for girls in 1906. She was also invited to be a Rector of this Lyceum until 1912. Then she lectured several subjects including Mathematics, which she never stopped, even after retirement.

Besides her activities as a lecturer and as a medical doctor she also published several books (related to education and poetry) at Coimbra, participating actively in the Educational Reform leadership by Carneiro Pacheco in 1936.

In spite of her monarchist and conservative profile, she was one of the three women (along with Mª Guardiola and Mª Cândida Parreira) invited by the government of Salazar maintaining cordial relationships between Salazar and the Queen Amélia de Orleães, with whom she always kept a friendly correspondence. She was deputy at the National Assembly with the age of 64. Some of her **parliamentary actions**:

- Law project to introduce hygienic and puericulture as subjects to be taught in every secondary school (1935).
- Creates Tropical Medicine Institute (1935).
- Creates a special support program to help poverty (1936)
- Creates special law for Fisherman Houses Project (1937)
- Construction of Justice Palace of Lisbon and Oporto (1938).
- Law projects for the regulation upon primary and secondary examinations as well as the introduction of fees for the High Schools.

She was also a correspondent member of the Lisbon Academy of Sciences.

German Case Study: the first Medical Doctor Woman

In the second half of the 19th century, women could already complete university studies in many countries and in Berlin in 1896, the Prussian Minister for Culture permitted women to have guest status at universities such as Berlin University (fig. 4) but nevertheless it was very difficult for them to become a physician.

Fig. 4: Berlin University – The Medical Faculty (1810).

In Berlin, women' s rights activist Helene Lange (1848-1930) offered courses for women beginning in 1898, thus giving the graduates their first pre-requisites for university study. In 1896, the Prussian Minister for Culture permitted women to have guest status at universities. Many professors and male students agreed, however: women did not belong at university!

There is a curious story about women and dissection that involves a renowned medical doctor, Wilhelm Waldeyer (1836-1921), who started university studies in mathematics and the natural sciences in nearby Göttingen. Soon after attending lectures by the famous anatomist Jakob Henle (1809–1885), the young Waldeyer was determined to become a lecturer in anatomy and therefore turned to medicine. He continued his studies in Greifswald and Berlin, where he graduated in 1862, and earned the title of medical doctor. He was made full professor of pathological anatomy in Breslau in 1867, still waiting for an opportunity to enter anatomy, his desired specialty. In 1883, he moved to the prestigious Chair of Anatomy in Berlin, now the Imperial capital.

One of Waldeyer's peculiarities that deserve mention here is his explicit opposition towards the admission of female students to medical school. Women studied medicine from as early as the 1830s in the USA and from 1864 in Switzerland. Prussia, however, which was still an administrative entity within the Empire, would not admit them to state exams until 1908, another nine years after the parliament of the German Empire had made a decision to this effect. Waldeyer tried to justify his opinions, which were certainly backward even for his time, by historical and "scientific" arguments. In a 15-page paper published in 1888, he held, e.g., that obstetrics, a long-time female domain, only flourished as a science when it came into the hands of men, and that the many women who came to power throughout history would testify against the view that women's abilities were simply restrained by society.

He added that according to "recent scientific evidence" the gyres of the male brain were more pronounced than those of female brains, leading to a larger cortical surface, the "substrate of our intellectual abilities" (Waldeyer, 1888).

It was obviously unthinkable for Waldeyer that women should enter the (then) male sphere of the dissection room and, perhaps even more shocking to him, that they should dissect men's bodies. It took several petitions of potential female students and the intervention of a minister for Waldeyer to finally allow female students into the anatomy laboratory, if only in a separate room and not taught by himself. In the Winter of 1904/05 the first 22 women (see fig. 6) therefore dissected under the supervision of Waldeyer's associate, Hans Virchow (1852-1940), the son of the famous Berlin pathologist Rudolph Virchow (1821-1902), (Stieve, 1942).

Hans Virchow took a strong stand concerning the question of the medical school for women and offered separate preparation courses for women in the "museum room" of the anatomical institute starting in 1904.

In fig. 6 we can see Elisabeth Litzmann (1883-1974) in the front to the right, as well as the interim report card from this student, dated from 5 November 1908, when Prussia finally gave women the right to full matriculation, and therefore also freed the way for female physicians. However, a regular academic career for women was only possible after 1920, when they were permitted to complete the postdoctoral qualification of a "Habilitation".

Fig. 5: Hans Virchow.

Fig. 6: Special dissection course for women (top) and Elisabeth Litzmann's Report card from November 1908 (below).

Rachel Hirsch (1870-1953) (fig. 7) was born in Frankfurt and studied at Zurich, Strasbourg and Leipzig. She was the first Medical Doctor woman in Germany because she got permission to practice medicine at Charité Hospital since 1903 when she started working with Dr. Kraus doing scientific works later published in the field of experimental physiology. Three years later in 1906, she discovered that solid particles are able to pass from the veins and arteries into urine (*Hirsch Effect*).

The results of her investigation were severely criticized, the result of which was that she had to give up her position. Only in 1908, Prussia gave women the right to full matriculation in Medical School and therefore also freed the way for female physicians, being Rachel Hirsch the first Prussian female medical professor in 1913. Her discovery, which had been so greatly criticized, was named after her. Many years later, she gave up her position and established a private practice in the Berlin district of Wilmersdorf.

Fig. 7: Rachel Hirsch in the laboratory (from Leo Baeck Institute[1]).

Under the Nazis, she found it increasingly difficult to work; in early October 1938 she left Germany and went to England, where she remained until her death on October 6th, 1953. Not allowed to practice in London, she underwent a serious crisis. When she died, she was impoverished. More than a decade later, she was posthumously admitted into the *"Gallery of famous Jewish scientists"*.

Conclusions

Scientific organizations have evolved exponentially during the last two centuries.

While scientific thinking developed according to his "logical and empirical needs" there was neither time nor space to recognize the "masculine mark" in the knowledge system.

This question was opened by philosophers, historians and sociologists by calling attention to the fact that scientific knowledge was influenced by the social and political context.

Therefore, social and political context influence the kind of knowledge produced by science and also "who" does science (Londa Schiebinger, 1999).

William Whewell (1794–1866), one of the most important and influential philosophers in nineteenth-century Britain wrote extensively on numerous subjects, including mechanics, mineralogy, geology, astronomy, political economy, theology, educational reform, international law, and architecture, as well as the works that remain the most well-known today in philosophy of science, history of science, and moral philosophy Whewell invented the terms "anode," "cathode," and "ion" for Faraday. Upon the request of the poet Coleridge in 1833, Whewell invented the English word "scientist"; before this time the only terms in use were "natural philosopher" and "man of science". While defining the word "scientist" Whewell in 1834 said:

---

1 Many of the works on display –including rare documents, unpublished manuscripts and critically acclaimed publications from the holdings of the Leo Baeck Institute– attest to the spirit, courage and competence of these largely unknown and unacknowledged women. While we may not know them by name, we do know that the feminist movement is but one aspect of their astonishing legacy.

"In fact, there is a "sex in our minds".

Almost 200 years later this situation still remains… if the sex is located in our minds or in our culture or in none of them, is still a controversial question!

However, it is not difficult to understand that while this question remains unsolved women will naturally feel uncomfortable in the world of professional science.

This is a tribute to the ingeniousness, creativity and perseverance with which Jewish women have shaped their destinies. Through necessity or choice, these women often became both catalysts for social and political changes and imaginative forerunners of science development.

Abstract

The archive and the library of the Spanish physician Pere Felip Monlau (1808-1871) are located in the Balearic Library in Palma of Majorca. This archive contains all the correspondence exchanged between Monlau, Spanish delegate in the three first International Sanitary Conferences, and the other delegates of the countries represented in the Conferences.

The archive has letters of Guglielmo Menis (1793-18??) a delegate from Austria, François Melier (1798-1866) from France, A. Costi from Greece, José Maria Grande (18??-1858) from Portugal, Mühling from Prussia, C. O. R. Rosenberger (1806-1866) and Eugene Pelikan (1824-1884) from Russia, Angelo Bo (1801-1874) from Sardinia, Pietro Betti (1784-1864) from Toscana, Giuseppe Carbonaro (1800-1858) from Two Sicilies, Bartoletti from Turkey, John Sutherland (1808-1891) from the United Kingdom and Agostino Cappello (1784-1858) from the Vatican State.

The aim of the paper is to analyze the information related to the fight against epidemics, mainly cholera, contained in these letters in order to evaluate its influence in the conclusions of the International Sanitary Conferences.

Pedro Felipe Monlau (1808-1871)[1] was the sanitary delegate for Spain at the first three international sanitary conferences held in Paris (23-7-1851/19-1-1852), Paris (9-4/30-8-1859) and Constantinople (13-2/26-9-1866). During these years and up until his death in 1871, he maintained a close relationship with the European hygienists and epidemiologists of the second half of the 19th century.

Following Monlau through his daily notes of the lectures, his correspondence, documents from the Medical Institute of Valencia(1841-1894) and its Bulletin (*Boletín del Instituto Médico Valenciano*, 1841-1896) and the Monitor of Health (*Monitor de la Salut*, 1858-1864) we can see how Monlau became friends with almost all of the sanitary delegates for the states represented in the ISCs[2] and with other Spanish and European professionals, friends of the above concerned about epidemiology and hygienism contacted by Monlau using the aforementioned means.

---

[1] Pedro Felipe Monlau Roca (1808-1871), born in Barcelona, began his studies at the Conciliar Seminary of Barcelona and subsequently studied science at the Royal Academy of Natural Sciences and Arts of Barcelona and at the Board of Trade of the same city. Finally he graduated and earned his doctorate at the School of Surgeons in 1830 and 1833 respectively. In parallel, he studied botany, French, Greek, English and Italian, knowledge of which he was to benefit from at a later time. In 1832 he went to work at the Military Hospital of Barcelona and in 1835 at the Royal Academy of Sciences and Arts in Barcelona as a lecturer in geography and chronology. During this time he declared himself politically as a progressive liberal by participating in journals such as *El Popular* (1834), and afterwards in *El Vapor* (1833-1837) and in *El Constitucional* (1837-1843), which he ran between 1835 -1836 and 1837 respectively. In 1837, following the victory in the general election of the moderate liberals (conservatives), he had to go into exile in Paris, where he remained until the progressive liberals won the elections in 1839. His exile in France, however, was extremely positive for Monlau's integral education, since it allowed him to come into contact with leading health professionals, scientists, and social agents in addition to providing first-hand knowledge of the progress of civilization. So he established contact with doctors and teachers at Parisian academic institutions, including Alfred Velpeau (1795-1867), Mateu Orfila (1787-1853), François Magendie (1783-1855), François Broussais (1772-1838), Pierre Gerdy (1797-1856), Philibert Roux (1780-1854), August Chomel (1788-1858), Jacques Lisfranc de St. Martin (1790-1841), Jules Cloquet (1790-1893), Achile Richard (1794-1852), Philippe Ricord (1799-1889), Joaquim Hysern (184-1883) and the liberal economist Adolphe Blanqui (1798-1854). The knowledge of all kinds which he picked up at this time would shortly be made known to Spanish citizens through various publications. Back in Barcelona in 1839, he returned to his classes at the Royal Academy of Sciences and Arts in Barcelona and in 1840 was appointed Professor of Literature and History at the University of Barcelona. In 1844, with a new moderate government in Madrid, he is banished to Valencia where he remained working as a doctor at the military hospital in the city. His stay in Valencia was to be another important milestone in his biography, as he struck up a deep friendship with the founding group of the Medical Institute of Valencia (*IMV*) (1841-1894) for instance Antoni Navarra (18??-1865), which meant he was able to use the *IMV* and its newsletter *BIMV* (1841-1896), as an Archimedean point to make his publications and activities known throughout Europe. At the end of 1846, with the aid of his friend the Majorcan doctor Ramon Frau (1795-1861), a moderate liberal and a Mason, at that time Director General of Military health, he made the pragmatic decision to collaborate with the moderates and moved to Madrid to join a committee responsible for drafting new regulations for military hospitals. From this last time on, Monlau moderated his way of expressing his health and social ideas and began a meteoric race to make his ideas known all over the world in such a way that his books can now be found in a large number of Spanish and European libraries ranging from nuns' convents to the main libraries of academic and scientific institutions. In 1847 he won the public exam for a chair in psychology and logic at the San Isidro Institute in Madrid (secondary school institute) and settled in Madrid once and for all. This same year, 1847, he was appointed secretary of the Health Council for the Kingdom (the highest advisory body on health) thanks again to the good offices of his old friend Ramon Frau and of his new friend Mateo Seoane who he coincided with in so many things. At the Council he coincided and established friendship with the other great Spanish hygienist Francisco Méndez Álvaro (1806-1883). These were the years that saw the introduction of the study of hygiene into secondary education and medical studies in Spain, and were also when Monlau published his most important books on hygiene. In 1850 he was appointed lecturer in psychology and logic at the Normal School of Philosophy. In 1851 he was appointed sanitary delegate for Spain at the first International Sanitary Conference (ISC) in Paris, likewise at the second one in Paris in 1859 and also in the one in Constantinople in 1866. Due to his participation in the ISCs he established a network of personal and scientific relationships across Europe, thus as well as the delegates at the ISCs, and as a result of these relationships, he was put in touch with the Frenchmen Michel Lévy (1809-1872) a famous hygienist, Antoine Barthelemy (Clot-Bey) (1793-1868) one of the most important epidemiologists of the time, and Brier Boismont (1798-1881) an important phrenologist; and also the Italians Francesco Torchio ((17? -1864), Gian Battista Massone (1817-1864) a hygienist and epidemiologist, Paolo Mantezzaga (1831 to 1910) a hygienist very similar in character to Monlau who influenced him very much, Salvatori Renzo (1800-1872) a hygienist and medicine historian, and the likewise hygienist and paediatrician Isacco Galligo (1822-1869). In 1857 he was appointed, at the same Normal School of Philosophy, Professor of Latin, Spanish, Limousin, and ancient Galician, simultaneously teaching this subject alongside logic and psychology. In 1858 he founded an emblematic journal on hygiene in Spain *El monitor de la Salud*, which he ran the whole time the journal was published, specifically until December 1864. Finally, with regard to his teaching work, in 1866 he was appointed professor of public hygiene and epidemiology for the doctoral studies in the Faculty of Medicine of the University of Madrid, but was stripped of it in 1868. As a result of the relationships established in the ISCs he was appointed member of many European academies of medicine and also received several medals for sanitary merit. At the same time, Monlau had developed a writing career that led him to be elected member of the Royal Academy of the Spanish Language in 1858 and of the Royal Academy of Moral and Political Sciences in 1870.

[2] International Sanitary Conferences.

Thus, we have been able to establish that as of the first ISC in Paris, a network of health professionals was steadily created - initially made up of sanitary delegates at the ISC - which, at times from opposing epidemiological and hygienic criteria, created a common state of opinion concerning epidemic diseases and how to eradicate them, through the exchange of letters, journals and books that were produced due to their knowledge at the ISC.

From this starting point which will be documented in the development of the research project, we seek to demonstrate that the personal opinions of the health professionals thus connected were decisive to the adoption of concordant health actions by the countries participating in the ISCs, and to their gradual emulation by the rest of the countries in the world.

The process that will be documented in subsequent communications where we will deal with all the ISCs, culminated in the creation in 1938 of a stable organization that covers practically all the countries in the World and which has been known since that date as the World Health Organization (WHO).

Starting then from the documentation contained in the personal Archives of Pere Felip Monlau and his own private library deposited in the Library of the Balearic Islands located in *La Real* Monastery in Palma de Mallorca, we have been able to conduct several research activities –in an initial first stage of this project– which have led us to investigate in archives and libraries in France, England, Italy and Spain in order to study the relationship of Pere Monlau with the sanitary delegates for the aforementioned countries as well as their relationships between each other, along with the influence that these relationships and the conclusions of the conferences produced on the sanitary decisions made in these countries after the successive ISCs.

Pere Felip Monlau, when the First International Conference in Paris was convened, already had a wide knowledge of publications related to the health of populations as such and of individuals in particular. Hence, in 1846 he had already *published Elementos de Higiene Privada* (Elements of Private hygiene) and in 1847 *Elementos de Higiene Publica* (Elements of Public Hygiene) published in two volumes that were widely distributed throughout Spain in public and private libraries and libraries belonging to universities, secondary school institutes, teacher training schools and church seminaries.

Fig. 1: Pere Felip Monlau.

Figure 2: Mateo Seoane Sobral.

He was introduced into the sanitary environments of Madrid thanks to his Catalan and Majorcan liberal doctor friends Pere Mata (1811-1877) and Ramon Frau (1895-1861), established in the capital some years before, as well as the likewise liberal doctor Mateo Seoane (1791-1870), Grand Commander of Spanish progressive Freemasonry. Thus we find him established in the "Health Council for the Kingdom of Spain" as of 1849, where he would remain until well into the 60's. In 1851 when the 1st ISC is convened in Paris (a city that Monlau knew very well both from a social and health point of view, as he had lived there in exile from 1837 to 1839), the president of the Health Council for the Kingdom (CSR)is Mateo Seoane, and Monlau is a member.

The Government appointed the journalist, playwright and liberal diplomat Antonio María Segovia (1808-1874) as the diplomatic delegate for Spain at the ISC and Pere Felip Monlau as the sanitary delegate, while at the same time it commissioned Mateo Seoane to coordinate the sanitary proposals to be defended at the ISC from the perspective of the presidency of the CSR[3].

This 1st ISC was held due to the major epidemics of yellow fever and plague that European states had suffered since the late 17th century, and the early 30's of the 19th century with regard to cholera[4].

Despite the different military and political difficulties that had taken place in France in recent decades, France was, in 1851, the great quintessential European power; French science was regarded as the leading scientific power and French the language of science and diplomacy as is English nowadays.

From this point, Louis Napoleon (1808-1873) President of the French Republic after numerous consultations convened the 1st ISC in Paris which opened on July 23th, 1851 with the following sanitary delegates from the accredited countries:

From Austria, Guglielmo Menis (1793-1853); from the Kingdom of the Two Sicilies, Giuseppe Carbonaro (1800-1858); from the Papal States, Agostino Cappello (1784-1858); from France, François Melies (1798-1866); from Greece, A. Costi; from Portugal, Jose Maria Grande (1799-1858); from the United Kingdom, John Sutherland (1808-1891); from Russia, Carl O. R. Rosenberger (1806-1866); from the Kingdom of Sardinia, Angelo Bo (1801-1874); from the Duchy of Tuscany, Pietro Betti (1784-1863); from Turkey, Bartoletti; and as sanitary secretary of the Conference, Antonin Jean Desormeaux (1815-1894).

At the Sanitary Conference in Paris in 1859 there were no sanitary representatives officially attending because the states were more concerned with controlling the possible resolutions and their consequences on trade rather than finding the best way to prevent diseases from spreading. It could be said that in the 1st Conference in Paris there was a balance between commercial interests and public health interests; and that in 1859 the dictates of commercial interests reached their highest point, whereas in 1866 the interests of public health began to impose themselves on the commercial ones.

The ISC of Constantinople in 1866 which opened on 13th February was attended by the following sanitary delegates:

From Austria, J. Polak and Sotto; from Belgium, the Count of Noidans; from Egypt, Selim Bey; from the Papal States, Ignaci Spadaro; from France, Antoine Fauvel (1813-1884); from Greece, A. Maccas; from Italy, Luigi Bossi (1809-1883) and G. Salvatori; from Persia, Sawas Effendi; from Portugal, Bernardino Antonio Gomez (1806-1877); from Prussia, Georg Hermann Mühlig (1826-1907); from the United Kingdom, Dalzel Edward Dickson (1816-1900) and Edward Goodeve (1816-1880); from Russia, Yevgeniy Ventseslavovich Pelikan (1824-1884) and A. Bykow and Lenz; from Turkey, Salih Effendi; and as sanitary secretary of the Conference, G. Naranzi (18?? -1877).

In an initial first stage of the research project we focus on the relationships established between Pere Felip Monlau and the sanitary professionals from Spain, France, Italy and the United Kingdom, and all of them between each other. Simultaneously we will study the influence that these relationships, discussions and the conclusions reached by the ISCs on the administrative and legislative provisions on public health that were put into practice in the above mentioned "States".

One objective of this project is to highlight the contribution of the health professionals in the ISCs through the free exchange of their personal knowledge which led the states to bring down the barriers to the free movement of knowledge and data on public health in their respective states, a fact which according to the documentation compiled makes quite clear that they were initially more than evident.

The Conferences lasted for many months and gave rise to many informal meetings between delegates and, in these, the calm exchange of points of views on the problems that had brought them together. This can be deduced from the letter (N-2) dated 18/07/1852 in Paris, written by Antonio María Segovia to the "First Secretary of State" (from the Ministry of Foreign Affairs) that we find in the AHD:[5]

> *... Coincidentally, two government delegates entered to present it at the same time, that is, Sir Magnetto, Consul General, (in Egypt) and Dr. Angelo Bo. The latter is a person of special*

---

[3] Health Council for the Kingdom (CSR). In the Council there was a "Special Commission for Epidemics".

[4] Shortly before, there had been other initiatives to convene a SC. This is evident from the document found in the *Archivo Historico Diplomatico* (AHD, Diplomatic Historical Archives) in Spain dated February 4th 1850, entitled *The Sardinian Government invites His Majesty to take part in the Health Congress that will meet in Livorno, sending a delegate*. This extensive document explains not only the initiative on behalf of the Kingdom of Sardinia, but that Spain also wanted to convene a meeting along the same lines, in which at least the other state in the Iberian Peninsula, Portugal, would participate because it was already obvious that some epidemics had spread to Spain from Portugal. The document draws attention to the fact that it is absolutely necessary for the Spanish consuls to immediately inform the Central Government of any epidemic outbreak detected within the territory of these consuls.

[5] TR 488 , file 001.

knowledge on epidemic diseases and health legislation; and last year wrote on behalf of the Commission of the General Council of Genoa Maritime Health[6] *a remarkable report on "quarantine against yellow fever from America", a printed copy of which I was able to obtain before my departure from Madrid. Mr. Conde Gallina welcomed me with the utmost delicacy and warmth; gave me fine offerings, and introduced the aforementioned delegates and me to each other. Making the most of such favourable attitudes, I raised in conversation the object of our journey, and bluntly asked the Sardinian commissioners what spirit they had come in. Dr. Bo, who seems highly well-informed, and who speaks with great ease (in his Tuscan language) spoke frankly, and with much warmth and zeal. The Minister also spoke, as did all those present for the space of about two hours, with this turning into a true preliminary, yet very important, conference, due to the interest that Sardinia has always shown on this point, and due to the influence that I foresee this Power will have at the Paris Conference ...*

Another highly illustrative letter (N-3) also found in the AHD is signed by Segovia on 23rd July 1851 and also addressed to the "First Secretary":

... The French Government in addition to the Hall of Sessions has prepared for the Conference a room where delegates can go directly to consult the large number of books, maps, sanitary regulations, reports, tariffs, and other documents collected for this event; what is more it has declared that it will provide anything else that is requested. In this special library-archive, all delegates have agreed to deposit all the documents they possess, and those requested from their governments; and I believe I am also in the position to appeal to Your Excellency to send me as soon as possible the regulations and tariffs in force in Spain, and also a duplicate of the Official Bulletins that make up part of the documentation of my instructions, and any other documents that Your Excellency may deem useful to illustrate the issues, and thus influence in the deliberation ...

With these two letters it can be clearly deduced that the Conferences (in this case the first one) which in addition to carrying out discussions around public health measures to be applied in case of epidemic diseases, were used to enrich the sanitary knowledge of all participants.

The Spanish delegates to the Congress of Paris in 1851 received at the end of August the following instructions dated August 14, 1851 drawn up by Mateo Seoane as president of the Health Council for the Kingdom:[7]

Instructions for the Spanish Delegates in the International Sanitary Conference held in Paris:

Health Council for the Kingdom

Hon. Mr.

In compliance with what was offered in a final report concerning the conferences of the Sanitary Congress currently held in Paris, this Council has issued the following instructions to the Spanish Delegates of Spain at this Congress.

This Council, in performing the assignment to draw up the instructions to serve as a rule to the Spanish Delegates at the Sanitary Congress, could do no less than take into account the need not to bind them to the point in which this could impede them of any action required to embrace or reject the proposals that are presented, especially when there is no room for consultation in doubtful cases. It is much more necessary to allow them sufficient freedom of action to fulfil their mission in the present case, as the true object of the French Government in convening the Sanitary Congress in Paris, has been doubtless to commit other governments to making as many concessions as they can possibly get out of them, in order to establish the sanitary measures in favour of trade in such a way that as it is not easy to directly remove the obstacles that exist at present, indirect measures can be gradually adopted in order to achieve this objective little by little. The main one of these indirect measures, which will be discussed later, is well known: but as it is difficult to foresee what other ones will be proposed, and as it is equally difficult to calculate what turn the discussions will take, it is necessary to leave to the wisdom and knowledge of the Delegates who, taking as a guide the general principles laid down by this Council and adopted by the Government, regarding the need, uniformity and sufficiency of maritime sanitary measures, may embrace all that is in accordance with these principles, and reject that which opposes them ...

---

[6] The specific book is the following: *Sulle quarentene contro la febbe gialla d'America e sulla inefficacia degli ordinamenti quarentenari della Francia: Relazione di una commissione creata dal Consiglio Generale di Sanità Marittima sedente in Genova /redatta dal d. re Angelo Bo ... relatore della Commissione*. Genova. Tipografia dei Fratelli Pagano. 1850.

[7] We Find the document in the papers belonging to Mateo Seoane in box 247 of the Monlau Archive in Balearic Library .

In view of this document from the main authority for public health in Spain (everything to do with public health depended on the Ministry of Interior) it could be said that the Spanish delegates at the first ISC had enough freedom when it came to expressing their opinions and defending their points of view or to refute or in to the opinions of other delegates, but this was not the reality. As the body which really decided the postures to be defended was the Ministry of Foreign Affairs of each participating state as we have seen in all the documentation in our possession compiled from the Diplomatic Historical Archive of the Ministry of Foreign Affairs in Spain, from the documentation concerning the ISCs found in the National Archives of the UK, from the documentation we have collected from the *Archivio Storico Diplomatico del Minnistero degli Affari Esteri* of the Italian Republic , and from documents that are in the Vatican Secret Archives or the *Archivio di Stato* in Naples. This means that the interests of state were above the interests of public health. This very point was one of the points of discussion prior to holding the Conferences, thus Spain along with other Mediterranean states formally called for the Government of France to guarantee that the needs of trade would not impede the adoption of sufficient public health measures to ensure no spread of disease.[8]

Our group, the GIHS at the UIB aims to publish, in the next two years, in high impact journals, the relationships of Pere Felip Monlau and Spanish sanitarians involved in hygiene and epidemiology, and their impact on Spanish sanitary legislation on public health between 1851 and 1871. The same will be done in relation to the British, French and Italians.

In a later stage, and if our initial theses are confirmed, we will continue to investigate these same relationships and influences on the other countries participating in the ISCs.

NATURALISTIC OBSERVATIONS IN APULIA DURING THE 19TH CENTURY. VINCENZO DE ROMITA AND ENRICO HILLYER GIGLIOLI

Peter ZELLER

Abstract

After 1861, year of the Italian Unity, a new and different circulation of goods, and then of naturalistic finds and scientific instruments, emerges among the different areas of the country. The south, far from Europe, poor in both material and intellectual resources, goes on finding its reference centre in Naples. In Naples there is the University and so people go to Naples to study and to teach.

In Naples there has been for some years the Zoological Station with the Aquarium, made by Anthon Dohrn (1872). But something happens also in the far province of Bari (Apulia), where a young scholar, Vincenzo de Romita, manages to create, with personal sacrifice, two collections: a naturalistic one and another of Neolithic finds. He goes down into the caves, catches snakes, and walks tens of miles looking for carved flint stones. But, most of all, he weaves an important exchange net with the most important scholars of his time. In particular, he is friend of Enrico Hillyer Giglioli, who studied at the London School of Mines where he knew Darwin and Huxley, and who was back from an adventurous travel around the world with the Magenta corvette. Twelve letters found in the La Specola Museum of Florence witness a decade of exchanges. Finally, Giglioli entrusts him the responsibility of writing the observations on the Apulia avifauna for the making of the First Report of the Results on the Ornithological Inquiry in Italy (1890). De Romita's collection; which soon reaches some notoriety, is the basis of a series of publications: Apulia avifauna (1883), Addition to the Apulia Ornithology (1890), New Additions to Apulia Ornithology (1900) and Materials for the Fauna of Bari (1900). This last one will be presented during the universal Exposition of Paris in 1900 inside the volume The Land of Bari from the historical, economical and naturalistic point of view realized by the Province of Bari.

The Mediterranean dream

Between the end of the 19th century and the beginning of the 20th century, observations and research initiatives in the naturalistic field increased in Italy and Europe. Southern Italy was, in this period, destination for foreign scholars, attracted by the Mediterranean faunal richness. Particularly, Naples and its gulf (but also Sicily) appealed to many scientists, most of them German, who, following Goethe, pursued “the South, the Sun, the orange gardens sung by Johann Wolfgang Goethe and set in music by Franz Schubert”[1] but they also knew they can count on the promises of an unexplored, full of life, sea.

The special compulsion to particular initiatives given by the debate caused by Darwin is to be added. It should be sufficient to remember, among the others, the creation of the Zoological Station and the attached Aquarius inaugurated by Anton Dohrn in Naples in 1874 (figure 1).

Fig. 1: The Zoological Station in Naples (1874).

There have already been native initiatives of research, even notable, before the south was affected by this “Mediterranean dream”, that led Haeckel among the “ostricari” (oystermen) in S. Lucia and generations of scholars to bow their heads on the microscopes of the Neapolitan laboratory. Think about the monumental work by Oronzio Gabriele Costa about the fauna in the Kingdom of Naples. You can find numerous southern scholars interested in natural sciences also in the post-unitary period.

Even if Naples remained the obliged reference and unavoidable destination of the intellectual immigration as it happened for the Apulian Salvatore Trinchese or Achille Costa, there were also figures who remained in such a way anchored to Apulia, doing a naturalistic inventory of it. The names of Achille Bruni from Barletta, Achille Barba from Salento, Alfonso Palanza from Abruzzo, the author of the *Flora della Terra di Bari* who taught at the Liceo Carmine Sylos in Bitonto, Antonio Jatta, lichen scholar, come to our mind. But the forgotten, or nearly, and the lost collections are many.

I would like to dedicate a bit of attention to one of these stories that sees scientific passion and personal sacrifice together with the desire to overcome cultural isolation by creating a wide and even international net of relations.

Vincenzo de Romita

Vincenzo de Romita (figure 2), son of Raffaele and Felicetta Laudati, was born in Bari the 23rd May 1838 at 22 via Palazzo di Città, a short walk from the white Saint Nicholas Basilica and nearby Mercantile place and the ancient walls, then directly overlooking the sea and housing inside the ships shelters.

He studied in Naples where he knew Achille Costa, who will remember him in his *Relazione di un viaggio nelle Calabrie fatto nella state del 1876*.[2]

> Having left Naples the evening of the 11th July by train, I stopped in Bari the 12th, being very uncomfortable going on towards Calabria. I spent a few hours in the city with Mr. Vincenzo de Romita, already scholar of our University and now professor of Natural History in that Technical Institute, who with zeal deals with the collection of the most particular and interesting things the region could offer him: objects I could observe, others in the Institute office, others in his particular collections. For example I could notice various species of birds not easy to find in southern Italy. Among the Reptiles he had the *Coluber leopardinus*, variety described by Pallas with the name of *Col. Lineatus*. Among the fish, a notable two-headed Shark foetus, a not common monstrosity in that class of Vertebrates. Finally, among the insects there was the *Cicindela dilacerata, D.c.j.*, which appeared for the first time in the Fauna of the Neapolitan provinces.

The collection Costa talks about is the naturalistic finds one, that the scholar, then aged thirty-eight, had started some years ago both privately and as a collection of didactic use at the “Reale Istituto tecnico e nautico”, where he had been teaching science since 1874. Later, in order to classify and describe the Apulian Fauna (with particular reference to ornithology), de Romita will publish *Avifauna pugliese* (1883), *Aggiunta all'Ornitologia pugliese* (1890), *Nuove aggiunte all'Ornitologia pugliese* (1900) and *Materiali per una fauna barese* (1900).

Fig. 2: Vincenzo de Romita (1838-1914).

During his youth he devoted himself with great enthusiasm and energy to search the countries of Canosa, Toritto,Terlizzi, Altamura, Cassano, Alberobello, Monopoli, Fasano, looking for Neolithic artefacts and moving further to Gargano and Basilicata. These excursions allowed him to set up a collection of more than one thousand and five hundred exemplars such as arrow heads, knives, spears, hatchets, scrapers. He presented a significant selection of them during the “Esposizione italiana di Antropologia ed Archeologia preistorica” (Italian Exposition of Prehistoric Anthropology and Archaeology).

The Province of Bari could so appear, not making a bad impression[3] on the other hand, during the exposition, which came alongside the International Congress of Bologna in 1870.

Zeller (edited by) *Vincenzo de Romita e il suo tempo,* Adda Editore, Bari 2010 , p. 4. The contribute of de Romita to the Exposition is also reported in L. Pigorini, *Relazione sulla Esposizione italiana di antropologia*,1871, pp. 30-31. See also: *Bull .paleontol.it*, II, 1876, p. 207.

In a booklet of 1876 named *Gli avanzi antistorici della provincia di Bari* he wanted to describe these researches of his own, the long soil searching, the findings emotion, the hard talks with the farmers who, considering the silica objects provided of "the virtue of keeping the evil eye away", appeared very reluctant to give them up.

"Not without great difficulties" –as he writes– "and using all kinds of persuasion, I sometimes succeeded in taking away an arrow head, handed down from generation to generation and attached of the strangest virtues." He proceeded from the fact that the province of Bari had been, from this point of view, not much studied "even if very rich in rock artefacts" and it had not had "so far someone who had designedly collected and studied the prehistoric archaeology treasures which it was throughout strewed with". And he came to a surprising result: "My researches were crowned by such an splendid outcome that it overcame my conceived hopes."[4]

The criteria he followed trying to date the finds on the basis of the possible remains of the ancient fauna were also, if one might say so, modern as: "trying to date the human artefacts when the fauna horizon which goes with the finds is missing you run the risk of judging rashly."[5] Starting from 1875, and for at least 10 years, de Romita had a correspondence with Enrico Hillyer Giglioli (figure 3), then director of the "La Specola" museum in Florence as the 12 letters kept in it attest.[6]

Enrico Hillyer Giglioli

Enrico Hillyer Giglioli studied in England as a young man at the Royal School of Mines, where he knew Charles Darwin, Thomas Huxley and Charles Lyell.

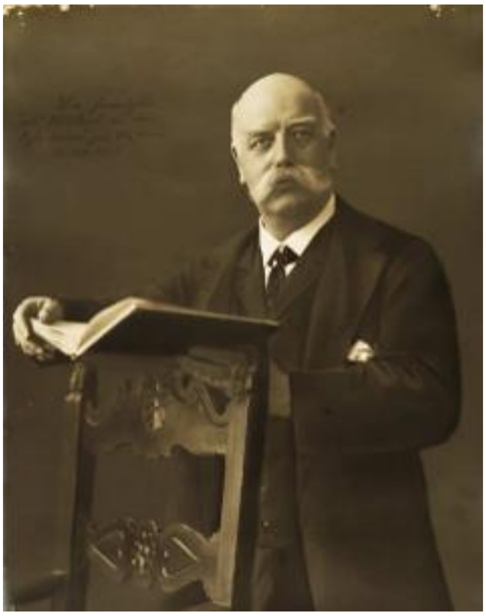

Fig. 3: Enrico Hillyer Giglioli (1845-1909).

He rather edited the publication of Huxley's lessons on the journal *Lancet* before being obliged to come back to Italy because of the missed renewal of his own grant.

The following year, aged only twenty, on the scientist and senator Filippo De Filippi's recommendation, he embarked the Magenta "pirocorvetta" for a voyage of circumnavigation around the world. In Hong Kong, on his way back, De Filippi, struck down by amoebic dysentery, died at the age of 53. At the end of the voyage Giglioli stayed for some time at the "Regio Museo Zoologico"(Royal Zoological Museum) to reorganize the wide collected material under the management of Michele Lessona, who by then had also replaced De Filippi in the role of Italian divulgator of Darwinism.

[4] *Ibidem*, p.4.

[5] *Ibidem*, p.7.

[6] See: *Vincenzo de Romita e il suo tempo*, cit.

Moved to Florence, in 1874 he was appointed full professor of Zoology and Compared Anatomy of the Vertebrates. He started to create, in those years, the Central Collection of the Italian Vertebrates as well as ethnographical and anthropological collections.

He wrote 400 scientific publications, most of which about natural sciences, among them *Zoologia della Magenta*, a wide report of his adventurous voyage, praised by the minister Quintino Sella. He made a lot of research trips to Europe and organized a wide net of relations also aimed at obtaining exemplars to improve his collections. A considerable part of his attention was occupied by ornithology. In 1879 he started the publication of the *Iconografia dell'Avifauna italica* (incomplete), the aim of which was that of offering a realistic picture of all the bird species in Italy. In 1881 he published two works about the Italian Avifauna and afterwards he organized an ornithological survey by sending modules to the observers all over Italy. The *Primo Resoconto dei Risultati dell'Inchiesta Ornitologica in Italia*, his first account of the results of the ornithological survey in Italy, was published in the years 1889-1890, while the *Secondo Resoconto dell'Inchiesta Ornitologica* in 1907. He died the 16th December 1909 after a heart attack.

The de Romita-Giglioli correspondence

The correspondence between de Romita and Hillyer Giglioli is mainly made of proposals of exemplars exchange or, sometimes, selling. However their personal relation went far from these negotiations and materialized into mutual visits. De Romita remembered in his *Materiali per una fauna barese* a work later presented in the Universal Exposition in Paris in 1900, one of his visit in Apulia:

> I have to thank the fortune of having accompanied the eminent professor during an excursion in Taranto for ichthyologic researches if I have the pleasure to number also this species (*Cygnus Bewickii*), native of the extreme north of Europe and Asia, in the *Avifauna pugliese*. In the "Swan pharmacy" we admired one exemplar which had been caught in the gulf of Taranto and properly in the Mar Piccolo during the winter of 1878.[7]

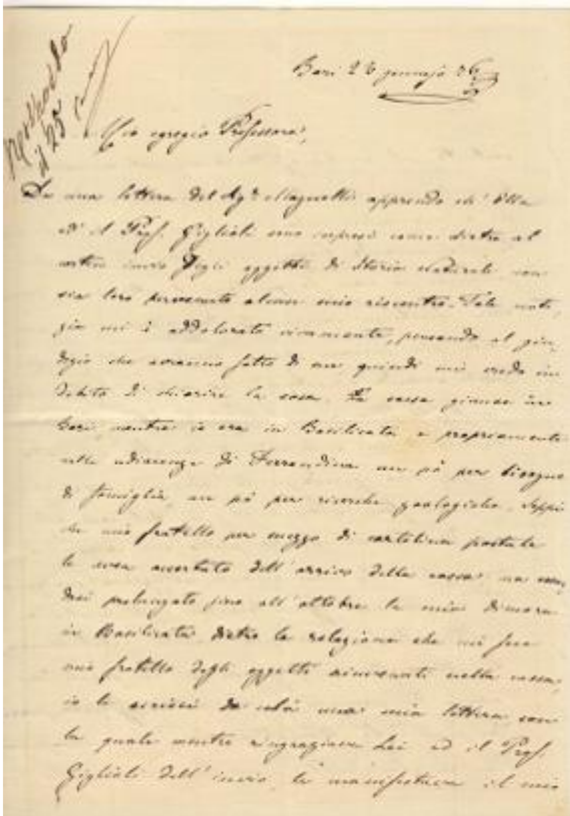

Fig. 4: A letter from the correspondence between de Romita and Hillyer Giglioli.

[7] *Materiali per una fauna barese*, p.63. Anastatic reprint in P. Zeller (edited by) *Vincenzo de Romita e il suo tempo*, cit.

We also know from the correspondence that de Romita submitted the proofs of the *Avifauna pugliese* to the younger but very famed professor for examination. In a letter of 1885 we can read:

> Finally my poor work about the Apulian Avifauna is at the printing house and within few days I will be able to collect the first proofs! I also would like to contribute to the development of the Italian ornithology; and if I succeed with this work I will let you and the experts judge. Meanwhile I would have a singular fortune if, before releasing it, I could submit it to you for examination, for this reason I will send you the proofs as soon as they are ready so that you may write your observations down in the margins. But this only if it would not cause you too much trouble, therefore I look forward to your adhesion.[8]

Actually the work was published only months later without the examination of the proofs:

> The printing of my memories about the Apulian birds embarrasses me a lot because of the typographer, who after leaving whole weeks pass without composing a word, when he in a rush has composed a sheet, he does not give me the necessary time to correct it thoughtfully. As it happened with the first sheets, for which it was not possible for me to submit them to your examination. Meanwhile I send them to you adding the composed pages, not yet printed. I will consider with great favour all the observations you will do about it and I will wait for the corrections of the part not yet published, with the hope of using it.[9]

Hillyer Giglioli was the representative of a prestigious research centre, provided with adequate means. "Not on another pact the poor can give to the rich, and I am very poor, and you are very rich", de Romita wrote him in March 1883, talking about the necessity for confidently waiting for the exchange compensations despite of the great delays.

In this symmetry, nevertheless, we surely know that Giglioli really appreciated the work of his "poor" colleague, so much that he got him to provide the data concerning Apulia for his famous ornithological survey. In the *Primo Resoconto dei risultati dell'inchiesta ornitologica in Italia* he wrote: "This list has been filled in by the eminent professor Vincenzo de Romita in Bari, author of an excellent work on the Apulian Avifauna published in Bari in 1884; in this list there are a lot of observations, unpublished so far."[10]

Also later, in the second report in 1907, he will mention him dozens of times.

Ultimately we can here register, as in the post-unitary context, the need for nets of cultural relationships is getting stronger in order to achieve a deep comprehension of the national territory and the local realities. In such a pattern both great initiatives, as Giglioli's survey aimed at evaluating the Italian faunal reality, and local but not isolated initiatives, directed to didactic and research aims, found their place.

De Romita's work (both the collections and the publications) gives us back the picture of Apulia as characterised by a richness of species, a biodiversity which can nowadays only appear as extraordinary. We can now read about the Great bustard (*Otis tarda*) again, here extinct, "this majestic bird, which was reasonably called the ostrich of Europe, not seldom appears in the Capitanata plains among the endless cultivated wheat fields […]." We can also read about the Little bustard (*Tetrax tetrax*), also disappeared, "which you can meet with more frequency and nesting in Apulia." About the beautiful Purple swamphen (*Porphyrio porphyrio*), de Romita writes: "two exemplars of this beautiful small bird ("rallo") were sent to prof. Giglioli, from the padule surrounding Lesina lake and, according to the eminent ornithologist, it may be sedentary and not rare there."[11]

Sightings of golden eagles, spotted eagles and *Bonelli*'s ones in Bitonto, Santo Spirito, Taranto, talk about a far-off time in which Apulian skies were crossed by the shapes of impressive birds of prey.

Worries about the excessive and indiscriminate destruction made by hunting were not already then extraneous to these observations. His critics are often direct and explicit, sometimes in the context of impressionistic or poetic descriptions as in the case of the robins which "are in winter the most beautiful characteristic ornament of the fields where there is thick vegetation […] and despite this fact their massacre by snares is really dreadful."

Talking, for example, about grebes he tells how:

> In winter much more than in autumn or in spring, you can see on the sea at a short distance from the shore some couples or a small number of this very moving creatures, singular as other congeners not only for their organization but for their essentially aquatic life. The bright white of their lower parts, the gracefulness of their movements, the really colourful poses they assume on the wave, their continuous diving and floating back to the surface cannot pass unnoticed and the passer-by cannot help stopping ecstatic in a beautiful winter day and admire the show. Unfortunately our hunters' lead often takes this enchantment away.[12]

The worries for the hunt destructiveness are shared also by other (not that many) scholars of the time such as Giacinto Martorelli, Joseph Whitaker, Cecilia Picchi, Giovanni Salvatori, Arturo Francelli.

Martorelli, for example, wishes "the preservation of our whole fauna, the components of which are all so linked by very complicated biological relations we still know very little about, that it would be very risky trying to cut any."[13] In the opening relation of the "Congresso Cinegetico" (Cynegetic Congress) in Rome the 12th November 1911, he admonishes: "Seeing continuously coming to us the innumerable crowds of passing birds with marvellous constancy of dates, without realizing their sensibly decreased number over the years, let us think their production was endless and we squandered killing them in millions."[14]

Ultimately, the post-unitary period appears signed not only by the highest impulse in constituting zoological collections but also by the first worries (then often disregarded) for preservation of a heritage of which we realize the extraordinary vastness only now. With the new collections, among which the one wanted by Hillyer Giglioli in Florence stands out (The Central Collection of the Italian Vertebrate Animals), stricter criteria of cataloguing are also needed. The labelling of each exemplar (date, place, gender, age), reported in a general catalogue, is substituting the custom according to which the information about date and place of collecting were generally omitted. Giglioli writes:

> Each species, when necessary, should be represented by the places in which it lives, in order to obtain precise knowledge about its local distribution. No piece will be admitted in the collection if it has not been determined, registered, catalogued and labelled, so that the collection is always well-ordered.[15]

De Romita's collection (figure 5), who takes care of placing the vernacular names next to the traditional classification in his catalogues, certainly represents this new trend as it constitutes an important example of the so widespread appearing of local collections (private, in schools or in religious institutes) outside the great academic and museum institutions.

Fig. 5: De Romita's collection in Bari, in the present day.

ERNA LESKY, GENERAL AND DIPLOMAT. NETWORKING AS A POWER TOOL FOR THE HISTORY OF MEDICINE

Felicitas SEEBACHER
Department of History, Faculty of Cultural Studies, Alpen-Adria-Universität Klagenfurt, AUSTRIA
felicitas.seebacher@uni-klu.ac.at

Abstract

Erna Lesky was the first female professor at the Medical Faculty of the University of Vienna. She was able to use perfectly the mainly male occupied behaviour patterns and power tools to her advantage on the way to the head of the Institute for the History of Medicine. Lesky knew how to demonstrate authority and power and how to gain allies. Diplomatically built up networks and an enormous determination for performance had stamped her career success. With publications focusing on the Vienna Medical School, Lesky marked the Austrian way of writing the history of medicine. Her methods, focusing on medical efforts, became standard, allowing no other modern, interdisciplinary access. This paper is a differentiated presentation of the career of a female physician and historian of medicine who broke with the traditional role model and perceptions of women in medicine.

A short biography of a female physician

Erna Klingenstein was born on the 22nd of May 1911 in Hartberg, Styria, a federal country of Austria. She took her A-levels at the Academic Gymnasium in Graz, the capital of the Austrian federal country Styria, in 1929. At school, she also became acquainted with her future husband, Albin Lesky, who was her teacher for Latin and Greek. Klingenstein decided to study medicine and graduated at the University of Vienna in 1936.[1] In 1938, Lesky divorced his first wife Dr. Grete Lesky[2] and married Klingenstein. Two years before, he was given the chair for classical philology at the University of Innsbruck. Erna Lesky worked as a physician at the pediatric clinic of Innsbruck from 1938 to 1940 and from 1940 to 1945 at the NSV mother and child home in Igls, the Tyrol, an institution founded by the National-Socialist Party.[3] In 1949, the couple moved to

Vienna,[4] where Lesky stepped out of the position of the "wife of a famous scientist" and began to manage her own career, with the full support of her husband. Her strategical thinking proved successful in establishing contacts, building up confidence and cultivating relationships with the intention to exchange relevant informations. Organizing power by intensive social networking became a key element of Lesky's science management.

Strategical thinking

Lesky was interested in the history of medicine, and through her husband linked up well in the Scientific Community of Austria, Germany and Switzerland. In 1949, Paul Diepgen, who represented the editorial office of the history of science journal *Centaurus* in Germany and which was soon to appear in Copenhagen, offered to publish articles written by Lesky.[5] Two years later, Lesky published *Die Zeugungs- und Vererbungslehren der Antike*[6] by the publishing house of the Austrian Academy of Sciences, which would later become her habilitation.[7] Lesky's husband, as a classical philologist, was able to support her research and supply her with literature accordingly. In this way, he offered his wife a strong academic backing.[8] Lesky planned to habilitate in the history of medicine before she had even enrolled for history studies at the University of Vienna. Lesky expected better chances in this humanities orientated medical subject, rather than in clinical subjects. There a female professor was hardly conceivable for the male professors, even in the middle of the 20th century.

Diepgen, Lesky's adviser and mentor, informed her out of his experience, "that she would have difficulties with the habilitation, without being the assistant of a professor of the history of medicine at her university".[9] The expert and provisional head of the Institute for the History of Medicine at Vienna University at this time was Leopold Schönbauer who already had a female assistant he needed and favoured: the internist Marlene Jantsch. Diepgen recommended Lesky "not to loose courage", because if he would intercede on his "initiative […] without request" of Schönbauer, he would only cause "harm". It would be better to ask an "influential member" of the Medical Faculty who would patronize her and ask him about her "qualification for the lectureship". Diepgen recommended her to use the "waiting period" until her habilitation by writing popular-scientific essays to make the history of the medicine popular in doctors' circles. "It has to be clear to ourselves", Diepgen explained, "that we must talk a little bit primitively before the public, if we want to promote the history of medicine for our medical colleagues".[10]

The woman behind

In 1956, Lesky gained a doctorate in history[11] and habilitated only one year later in the history of medicine. On the same day as Lesky habilitated, her competitor, Jantsch, qualified as a professor.[12] The scientific career-path of Marlene Jantsch, née Ratzersdorfer, is a demonstrative example of the exploitation of the working capacity and willingness of female physicians. Six years younger than Lesky, she was born on the 26th September 1917, in Osterwieck, Germany, but took her A-levels at the Girls Grammar School in Döbling, Vienna, in 1936. On the 26th July 1941, she graduated from the Medical Faculty of the University of Vienna and became an internist at the First Surgical Clinic of the General Hospital in Vienna, chaired by Schönbauer. As Schönbauer's personal assistant she wrote numerous essays and articles in the history of

medicine, all of which were not published under her name, but his. Together with her husband Hans Jantsch, she researched for Schönbauer's book *Das medizinische Wien*[13] which was published in 1944 but once again, only by Schönbauer. None of them were named as authors. Jantsch supervised different departments at the Josephinum,[14] the former Military Medical Academy, where the Institute for the History of Medicine was housed now. There Schönbauer was the provisional head from 1944 to 1960.[15] Throughout this time, Jantsch remained "the woman behind". It was only after 1948 that Jantsch was named for the first time as an author in publications of the Viennese Institute for the History of Medicine.[16]

Referring to Lisa Fischer, men constructed the reality in science and had the "power of definition". If women succeeded in developing a self-image, contrary to "the male external definition", they had to suppress it in order "to maintain the patriarchal system".[17] Female physicians at the Medical Faculty of the University of Vienna did not succeed in reaching academic top positions till the middle of the 20th century. They were assigned to scientific auxiliary services and worked on publications which were published under the name of the male superior. Their knowledge was used, success was male encoded.

The "habilitation war"

Due to their different social environments and political views, Lesky and Jantsch also held contrary ideas as to their 'female' roles in medicine and the history of medicine.[18] Lesky did not range into the existing system, but broke with the traditional role model and perceptions of women in medicine. For Schönbauer she was, compared to Jantsch, less qualified for a habilitation in the history of the medicine. He classified Lesky as a "historian of philology" and not as a historian of medicine.[19] Lesky did not allow this comment to discourage her. Because Schönbauer had forbidden her to give lectures at the Josephinum, the former Military Medical Academy, where the Institute for the History of Medicine was housed, Lesky began in 1957 to lecture at Richard Bieling's Institute of Hygiene, University of Vienna. [20]

The "habilitation war", as the historian of medicine, Erwin H. Ackerknecht, calls the conflicts in his private correspondence with Lesky, concerning the professional and personal acceptance of the historian of medicine on the terrain of the Viennese Medical Faculty,[21] was won by diplomatically built up networks and an enormous determination for performance. These social competences influenced the decision of the Medical Faculty and while Jantsch remained bonded to Schönbauer, Lesky established international contacts. She integrated well into a scientific community of male order. Her correspondence with historians of medicine in Europe and the USA proves how extremely well she was able to build up relationships. In the search for expert opinions according to her ability to become a professor, she remained clever, but ambitious. In contrast to Jantsch, Lesky used the male occupied instruments of power and science policy strategically to conquer a man's domain.[22] She was able to negotiate her way through the medical faculty and successfully break up the old structures which existed there. Michael Hubenstorf deals with this conflict for the first time in the essay *Success and tragedy*

21 Erwin ACKERKNECHT, letter to Erna Lesky, 6th November 1956. In: Estate of Erna Lesky, handwriting- collection 4.700/5 (Institute for the History of Medicine, Medical University of Vienna). Ackerknecht found it sad that the "habilitation war" was so embarrassing for Lesky´s scientific work.

22 Lesky´s private and professional correspondence is an important source to reconstruct her career steps up to the professorship.

of a historian of medicine.[23] According to Sabine Schleiermacher, the chosen career-paths of female physicians would be understood easier, if the "decision-making processes" were seen in their "relations to women as well as to men". Only then could "difference and equality" be made clear.[24]

During the era of National-Socialism, Schönbauer was a member of the NSDAP. Nevertheless, immediately after 1945 he tried to get rid of this stigma by asking socialist politicians, like vice chancellor Adolf Schärf, to intervene in the governement.[25] However, Lesky, working for a national-socialist institution as well, found support from former members of the national-socialist party and in the Christian-democratic political sphere around her husband. The classification of Lesky in a political category could make her career more understandable.

Lesky's "reconquered Josephinum"

In October 1960, Lesky became the manager of the 'Josephinum', though at the beginning without a salary. After receiving calls from the Free University of Berlin, the University of Göttingen and the University of Hamburg, as well as having numerous publications, Lesky now had enough qualifications to become an associate professor in 1962. In 1964, she represented the Medical Faculty of the University of Vienna at the 600th anniversary of the University of Cracow, together with the rector for the academic year 1963/64, Albin Lesky.[26] Erna Lesky restructured the Institute for the History of Medicine, organized numerous conferences and international congresses whereby she presented 'her' Viennese institute to the scientific community. On the occasion of the six-hundred-years celebration of the University of Vienna in 1965, Lesky invited the surgeon Lorenz Böhler to her "reconquered Josephinum" with its precious collections and libraries.[27] She became an internationally recognized science organizer. The historian of medicine attended international conferences as part of networking in science to present her research results to acknowledged physicians and historians of medicine.[28] While Lesky was promoted up to the habilitation mainly by historians of medicine from abroad, she was able to win, with a lot of energy, prestige for her call from institutions in Austria and representatives of the Federal Government.[29] In 1966, Lesky received a chair at the Medical Faculty of the University of Vienna. She emphasized impressively that she was the first female professor since the university was founded in 1365.[30] In international comparisons, this was extremely late. Peter Voswinckel states that the Harvard Medical School had its "first female faculty member" with Alice Hamilton in 1919. In 1920, Winifred Clara Cullins received a chair of physiology in England. Even in Germany, Selma Meyer became professor for pediatrics in 1922.[31]

Due to consistent urging at the Ministry of Education in Austria and by successful sponsorship of the Welcome Trust in London, the "big doyenne" of the history of the Viennese Medical School put through a complete renovation and re-orientation of the Institute for the History of Medicine at the University of Vienna. Lesky knew how to derive personal benefits for her representative institute from her international networks. The Josephinum became the centre for the Austrian historiography of medicine, also because the other medical faculties at universities in Austria did not establish their own

institutes for the history of the medicine.[32] In general, the history of science in Austria shows that, compared to other European countries, there is a big deficit: not before 2008 did Friedrich Stadler receive the first chair of history and philosophy of science at the University of Vienna.[33]

The "big doyenne" of the history of the Viennese Medical School

Leskys diligence and engagement for the history of medicine were reflected in her publications. Her '*opus magnum*', *The Vienna Medical School of the 19th Century*,[34] was first published in 1965, the second edition appeared in 1978 and in 1976 it was published in English.[35] It is certainly one of the high quality standard works of history of medicine and will remain so "for a long time" says Karl Sablik, one of Lesky's former assistants.[36] Lesky's mainly sources-oriented methodology which concentrated on ideas and institutions, still excluded the sociological and political context of medical developments and institutional conflicts. Her biographies of physicians often remain heroic epics that focus on medical achievements. Sablik, who received the first lectureship in the social history of medicine in German-speaking countries in 1989, noted with regret, that an interdisciplinary re-orientation of the Institute for the History of Medicine in Vienna was prevented by Lesky.[37] Thomas N. Burg is convinced that Lesky had "paralyzed" the development of newer research attempts, especially as outside of the Medical Faculty of the University Vienna, hardly any research in the history of medicine took place in Austria. As an extraordinary and full professor at the Medical Faculty, Lesky determined "*qua persona*", what had to be understood by the history of medicine in Austria until the end of the 1970s.[38]

Albin Lesky was a full member of the Austrian Academy of Sciences and was president in 1969/70, while Erna Lesky was only appointed a corresponding member. In 1973, she was elected an honorary member of the Austrian Academy of Sciences,[39] however, the German Academy of Scientists the *Leopoldina*, appointed Lesky as a full member on 24th November 1965.[40] In 1970, she was elected the "first female senator", a representative of her region.[41] Memberships and important positions in scientific organizations have always been an important part in the advancement of science and science communications. In 1979 Lesky applied for early retirement and moved to Innsbruck.[42] Hubenstorf, who was at this time a medical student, had the impression in personal conversations with Lesky, that she was not ready to support the university reform of 1975, which was essentially aimed at the co-determination and new organisation of the universities. Participation of students in university politics was unimaginable to Lesky.[43] "Behind me is nothing", she said to her assistant Manfred Skopec, before she left the institute.[44] Lesky "found it extremely difficult to part from the institution which she had

rebuilt so sucessfully after the Second Wold War and to hand over the reigns to a successor".[45] Because of her authoritarian leadership, professor Lesky was called by her assistants secretly "the general",[46] highlighting the 19th century prejudice that medical studies for women were "rather harmful, since it produces masculine characteristics".[47]

In 1985 Lesky attended the 200th anniversary of the Josephinum and showed the Austrian President, Rudolf Kirchschläger, once more the treasures of the Institute for the History of Medicine in Vienna. Helmut Wyklicky, her former associate professor and successor on the chair for the History of Medicine, Medical Faculty Vienna,[48] found it sad, "to see the lady [leaving] her former domain, mortally ill and lonely […]. She died in Innsbruck the following year".[49] In 1991, Salome Waelsch, professor of Genetics at the Albert Einstein College of Medicine, analysed women in their academic careers in medicine from the experience of half a century. Women were "more intuitive, more imaginative [and] more idealistic" than men in their access to the sciences.[50] They disposed an "extreme emphasis on causality, on one thing causing something else to happen". Referring to Waelsch, "Attention to causality" is not a purely masculine quality.[51] Out of her experience Waelsch noticed that women in medicine "are as competitive as men". "They were equal to men concerning competitiveness in the sciences".[52] Hence, for Regula Leemann neither the scientific culture nor the structures of the academic organisations were gender-neutral. Due to the high prestige, which professors of medicine and the doctor's profession had in society in general, they still operated "with gender-stereotypical social allocations" of the 19th century. A woman who tried to penetrate into the "social space", where men strengthen their power in historical tradition, was almost forced to act after their values. The "homo-social science culture of medical faculties accepted the other gender only slowly". This led to the result that "an equality of the careers of women and men was prevented or became at least complicated"[53]

Conclusion

This paper discussed whether the research-results of the psychologist Guido Strunk, Research Institute for Health Management and Health Economics at the Vienna University of Economics, are valid for Lesky, too. His provocative hypothesis is: "A woman must be a man to make a career".[54] Economists make a distinction between subjective and objective career success. The subjective success expresses itself in the satisfaction with the career and the acquired respect in the professional sphere, the so-called ascribed success. However, the objective career success becomes visible in the salary and the management responsibility as well as the number of the subordinated employees.[55] Lesky was a highly respected historian of medicine. She managed to succeed in a man's domain through diplomatic networking. Self-representation, performance, leadership motivation, and competitive orientation, all determined her career success. Her objective career success was, compared to medical professors, heading a clinic, small.

Whether it is possible to realize a desired career depends on various factors, mainly on the personality structure and the motivation to reach the goal.[56] Factors of influence on career are the place of residence during childhood, the educational level and social layer of the parents and the social origin.[57] Focusing on Erna Lesky's career, the following factors become visible: Lesky spent her childhood in a small town with a rural environment. Her family belonged to the lower middle class. But because Lesky attended a Grammar school in a capital, she had the chance to use social mobility through education.

Further factors influencing Lesky's career were a very good conscientiousness and capacity for self-representation, high flexibility and achievement motivation. Her leadership motivation and competitive orientation were very good too, but Lesky showed only little interpersonal skills towards her assistents. She was not team orientated and did not have as much of an emotional stability as she pretended to.[58] As she grew up in the inter-war time, this might be understandable. Thus, for the career to succeed, the following factors were crucial for Lesky: She was very good in making friends and allies, in establishing and maintaining contacts. She understood how to emphasize her own skills and ideas.[59] To conclude, her career tactical behaviour was excellent.[60]

Comparing the careers of Jantsch and Lesky a discourse opens. Aurelija Novelskaite stated in her paper, given in 2006 at the Prague conference "Science policies meet reality", three different types of female access to an academic career. She discerned between "independent initiators, dependent followers and contended stayers". "Independent initiators" act and react actively. In interviews they told her: "I wanted to do it and I did that, you have to choose or I have just decided". They were highly motivated. "Dependent followers" and "contended stayers" act and react passively. They told Novelskaite: "One must be chosen, one should be patient and wait till her time comes or it happened in natural course". They thought they were "lucky".[61]

Jantsch applied to the strategy of dependent followers: Her research issue came from the field of Schönbauer. He conducted her research in the history of medicine. Jantsch was assigned to his research. She worked hard as well, but her main career-related decisions were taken by others. In contrary, Lesky followed the strategy of independent initiators. She knew that she would "get the chair, now or never". Independent initiators work hard continuously and take the main decisions independently. Lesky began her career, dependent on her husband, his research and his international relations, as a dependent follower. She became an independent initiator by her indomitable will.[62] However, nearly fifty years ago, she also had the possibility to stay in a leading position, because there was "the man behind", her husband Albin Lesky.[63]

HOW COULD RUSSIAN INTELLECTUAL WOMEN CONTRIBUTE TO AGRICULTURE? –CIRCULATION OF IDEAS IN EDUCATION AND CAREER DEVELOPMENT OF WOMEN AGRONOMISTS, LATE 19TH - EARLY 20TH CENTURY

Olga Yu. ELINA
Institute for the History of Science and Technology, Russian Academy of Sciences, Moscow, RUSSIA
olgaelina@mail.ru

Abstract

In the second half of the 19th century, Russia, compared to the other European countries and the USA, faced a rather disturbing situation regarding women high education and career opportunities. Universities as well as agricultural institutes were still forbidden for women; a few specialized institutes prepared mostly 'educated housewives', and only later opened up for future physicians and teachers. There were a few women enthusiasts who managed to receive special permission from both the Ministry of Agriculture and the Ministry of Education to enter Moscow Agricultural institute. Pioneers of the movement Mariya S. Bevad and Anna K. Kosto-Sudakovich became the first Russian women agronomic scientists.

In the end of the 19th century, the great hope for Russian women with passion for agricultural science became the establishment of an Association (Society) for the Advancement of Women's Agricultural Education (AAWAE). The AAWAE was set up in 1889 by men of liberal views, led by professor of agricultural science Ivan A. Stebut. This association became the first in Russia in the field of agriculture to give women full membership (in other associations women were only allowed to attend public lectures and entertainments). One of the most active female members was Nadezhda P. Dolgova, who lectured extensively on the development of women's agricultural education. She travelled around Europe, met her women colleagues to get information on the subject, and wrote a lot of articles and books on agricultural education abroad. As a result of the AAWAE activity, High Agricultural Courses for Women were set up in St. Petersburg (1904), Moscow (1908), and other cities. In the 1910s about 400 women graduated from these institutions every year to become agronomists and agricultural scientists.

The presented paper examines for the first time the circulation of ideas and the formation of networks in the field of women agricultural education and career opportunities in Russia.

Gender asymmetry marked the development of science and education until the second part of the 19th century. It was especially pronounced in Russia. Compared to the other European countries and the USA, Russia faced disturbing situation regarding women's high education and career opportunities, which became critical in the agricultural science.[1]

Universities as well as agricultural institutes were forbidden for women; few specialized institutes prepared mostly 'educated housewives', and only in late 19th century opened up for future physicians and teachers. There were some women enthusiasts who managed to receive education abroad, mostly in Switzerland. For example, in the 1870s over 100 Russian women registered for medical study in Swiss universities and Paris.[2] These early pioneers, many of whom formed enduring friendships with their West European colleagues, became the leaders of Russian *women's liberation movement* and opened the doors to the acceptance of women as fellow students along with men into high school environment.

Attending lectures in agronomy for Russian women met extreme obstacles both of psychological and bureaucratic character.

In spite of the state's status as a *country of peasants and agriculture*, in mid 19th century Russian agronomy was not considered as a prestigious area of education and scientific career for nobility who dominated universities. It was true for both male and female discourses. Things changed after abolition of serfdom and other modernizing improvements in the period of the Great Reforms. In the 1860s - 1870s young generation of *raznochintzy* –intellectuals of non-aristocratic descent, usually from merchants and clerics– came to high school. They established a *fashion* for so-called *going to peasants* (practical enlightenment work in the countryside) and developed profound interest in natural sciences' and agronomy education. These ideas attracted many young women, mostly from aristocracy. Thus the circulation of education and career ideas in Russia took place not only in gender space; these ideas were also transferred between social clusters.[3]

However, young ladies' passion for agriculture met uncompromising protest from their noble families. While a decision to attend university lectures was a disappointment for parents (who traditionally regarded daughter's future only in terms of marriage), intention to become an agronomist disgusted, led to family crises and resulted in dramatic severance, fictive marriages to avoid ruined reputation, etc.

Bureaucratic obstacles looked even more serious. Career of an agronomist was traditionally regarded as an exclusively male occupation. Spending half a year doing field experiments and improving peasant farming in Russian backward countryside seemed physically inappropriate for women. This stereotype was changing very slowly especially in bureaucratic circles. That's why for a female candidate to enter the agricultural high school demanded first to apply for a special permission from the Ministry of Agriculture (which could be obtained only through informal channels with assistance of high-ranking relatives etc.); for some schools the permission from the Ministry of Education was also necessary. In case of a positive resolution ("on the judgment of the institute's management") the second step was to persuade the director, the dean, and finally individual professors to give permission to attend their courses.[4]

These insuperable barriers explain why just few women enthusiasts managed to clear a hurdle. I found only two files of the female-students in the archive of Moscow Agricultural Institute for the 19th century. As their files tell us, they received special permission personally from the minister of agriculture Aleksey S. Ermolov (who was known for liberal perception of the question[5]) and entered Moscow Agricultural Institute in late 1890s. These pioneers were Mariya S. Bevad and Anna K. Kosto-Sudakovich who became the first Russian women agronomists. Unfortunately I couldn't find any traces of their further careers in agronomy.

In the end of the 19th century agricultural science began growing in prestige, mostly due to its promotion by Russian agricultural scientific societies. And due to activities of *zemstvo* –local public self-governed administrations– which established numerous agricultural experiment stations and supported agronomists in provinces.

At the same period the great hope for Russian women became the establishment of an Association for the Advancement of Women's Agricultural Education (AAWAE) –a forum for discussing and lobbing on an education reform. The AAWAE was founded in 1899 and was led by the renowned professor of agriculture Ivan A. Stebut.

During his long career in agricultural science, Stebut published a number of articles and books on the problem of agricultural education for women in Russia. His writings directly influenced the formation of the association. In 1891 at the Second Conference for the Development of Technical Education, Stebut presented a paper, in which he argued the necessity to set up a special body for assistance to agricultural education of women. The paper was published immediately in a special issue of a popular weekly *Russkie Vedomosty* (Russian Gazette) entitled "Agricultural Education for Women, its Significance, and Means of its Realization".[6]

Stebut's ideas were echoed by other male professors of liberal views who also wished Russian women to enter the sphere of education and career in agriculture. Among them were Alexey F. Fortunatov, Dmitriy N. Pryanishnikov, and also Boris N. Klingen, who published intensively on the question; the citation from his books I use as a *key question* in the subtitle of my paper.[7]

7 Klingen, I. *The Role of female educated member of agricultural community in the modernization of Russian countryside*. St. Petersburg, 1903.

However important the male initiative was in the creation of the AAWAE, the major role in its activities was played by female members. The Council of the Association was formed exclusively of women. The most active female members were agronomist Nadezhda P. Dolgova, physician Anna K. Malyarevskaya, and also leaders of Russian *women's liberation movement* Anna P. Phylosophova and Varvara P. Tarnovskaya.

The celebrated example of a woman challenging Russian women's inferior status in education was Anna P. Phylosophova. As her colleague A. Tyrkova wrote, "she was respected for all that she had consistently done for the diffusion of ideas of women's education –from supporting young girls who decided to enter the universities to creation of famous Besstuzhevskiye High Courses for Women in St. Petersburg".[8] In spite of her age (she was over 60 at that time), Phylosophova became a powerful figure in the AAWAE providing it with organizational knowledge and financial support (Phylosophova belonged to Russian aristocracy and many *decision makers* and financial *bigwigs* –high rank bureaucrats, members of the Tsar's family– were her close friends).

Fig. 3: Anna P. Phylosophova (1837–1912), an activist of women liberation movement, one of the founders of Besstuzhevskiye High Courses for Women in St. Petersburg.

The intellectual centrepiece of the Association was Nadezhda P. Dolgova. She was the only Russian female author who wrote intensively on women's agricultural education abroad.[9] Dolgova graduated from Geneva University and spent some time travelling Europe where she met her colleagues and gathered information on the subject. She also attended the

First World Women's Congress at the World Fair in Chicago in 1893. Later she returned to Russia and lectured extensively on the development of women's agricultural education in the country.

The Association supported private agricultural schools for girls which were set up in the 1880s .- 1890s mostly by women-landowners in their private estates. The most interesting example was Preobrazhenskaya School in Chernigov province founded by Anna N. Neplyueva and her daughters. Such a school enabled girls (from peasant families mostly) to get primary education and special knowledge and practice in agricultural subjects like farming, horticulture, husbandry. Some of Neplyueva's students tended to continue education in gymnasia and later in high school financed and encouraged by the patroness.[10]

The key result of the AAWAE activity, however, was getting a permission to create the first private high school in agriculture. In 1904 High Agricultural Courses for Women were set up in St. Petersburg, named after Stebut next year.

In 1908 Moscow High Courses for Women started their teaching activity due to patronage of Countess S.K. Golitsina. The institution was headed by Stebut's pupil Dmitri N. Pryanishnikov; other professors were renowned Russian scientists A.F. Fortunatov, G.M. Turskiy, A.G. Doyarenko, N.I. Vavilov. Later the same was done in Saratov (1913), Novocherkassk (1916) and other places. There also appeared agricultural high schools for both genders (Petersburg Agricultural Courses, 1906). All these institutions were non-governmental, i.e. created by individual patrons or due to public assistance.

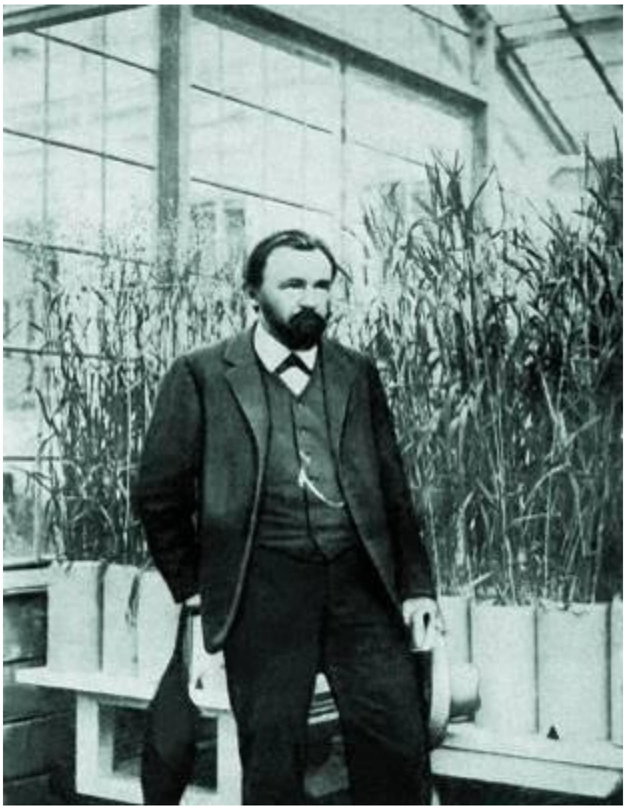

Fig. 4: Dmitriy N. Pryanishnikov (1865–1948), professor of agriculture, director of Moscow High Agricultural Courses for Women.

Students for the courses were recruited mostly from families of merchants, or clerics; many of them were daughters of university and agricultural schools professors who belonged to impoverished estate gentry or personal gentry. There was no disagreement in their families concerning young ladies' future occupation. Female agronomic students were emancipated persons; some of them looked rather provocative cutting their hair and refusing to wear traditional women's hats.[11]

There were some women among the professors of the courses. I would like to mention two of them that lectured at Stebut Courses. The first one was Nadezhda P. Dolgova, who became a deputy director of the Courses. The second one

[11] See a discussion on the question in: Yukina, I. *Russian women's liberation movement*. S. Peterburg: Aleteya, 2007.

was a graduate of the courses Sofia L. Ivanova, who was appointed to hold summer practical course in plant breeding –a new discipline for Russian agricultural science which demanded from a professor profound knowledge and sophisticated training. Male professors were agronomist V.E. Brunst, meteorologist P.S. Brounov, chemist G.N. Bong, plant breeder N.R. Nedokuchaev, and zoologist S.S. Averintsev.

Fig. 5: Ivan A. Stebut (on the steps, stands left) and Nadezhda P. Dolgova (next to Stebut) after the ceremony of the opening of Agricultural Courses, September 1904.

The number of female students was growing every year. The dynamics of students' numbers at St. Petersburg Agricultural Courses for Women is: 1907/08 – 196 students; 1913/14 – 525; 1917 – 1200.

The statistics for total number of female students for all schools was even more impressing. For ten years their number rose in more than ten times: in 1907/08 – 258 students; 1913/14 – 1150; in 1917 – 2773, or ten times as much. However, this considerable number looks rather modest, even poor in comparison with a number of male students; in percentage these numbers are 3.5 % for women and 96.5% for men. Meanwhile, in 1910s from 400 to 500 women graduated from agricultural high schools every year with a diploma to become agronomists and agricultural scientists.[12]

It goes without saying that field summer practices at specialized agricultural stations were of crucial importance for future agronomists. But it was rather difficult for newly established schools (always restricted in money) to find additional funding for organizing their own experimental plots. Only Stebut Courses managed to set up their private station.

In other cases it was only the assistance by state high schools and agricultural experiment stations (which were for granted *male institutions*) that helped to settle the problem. For example, students of Moscow High Courses for Women were having their summer practical courses at Butyrskaya experimental farm of Moscow Agricultural Institute and at some *zemstvo* agricultural experiment stations of the Central Region.

Naturally female graduates of the courses were invited to serve as agronomists and researchers at these stations (for example, at Mysovo station set up by mutual patronage of Moscow *zemstvo* and the government).

Usually they occupied not very high positions and could not pretend to rise further than head of laboratory (department). It is interesting that even in Soviet Russia, remarkable for its high-ranked women, in natural sciences, education, diplomacy, etc. at least until the Second World War female agronomists still belonged mostly to assisting scientific staff. This perhaps could be explained by traditional perception of occupation in agronomy as a *male* one.

Fig. 6: Students of Moscow High Agricultural Courses for Women.
Summer field lessons at Butyrskaya experimental farm, July-August 1910.

To conclude, I would like to stress that ideas of *entering women into agriculture*, or *necessity of agriculture for women*, circulated both in international and Russian national gender spaces; these ideas were as well transferred between social clusters – from *raznochintsy* to *aristocracy*. My argument is also that private patronage and public assistance became the key element in the development of female agricultural education. In spite of rapid growth of number of female students in agronomy, the career opportunities for women agronomists for years remained rather modest.

So in the presented paper I tried to examine the development of networks and the formation of institutions in the field of women agricultural education and career opportunities in Russia.

INTERNATIONAL NETWORKS FOR SUPPORTING SCIENTIFIC CAREERS OF WOMEN IN SPAIN, IN THE FIRST THIRD OF THE 20TH CENTURY

Abstract

In the early twentieth century, mobility for scientific training was not easy, let alone for Spanish women, who only gained access to university on an equal basis as men in 1910. The Board for Advanced Studies and Scientific Research (JAE in its Spanish acronym), the institution charged with the Spanish scientific policies since 1907 until the Spanish Civil War (1936-1939), played a key role in the careers of Spanish scientists by awarding them fellowships to travel and stays abroad. For careers of Spanish women scientists, besides the JAE, some networks of international solidarity for women were important too.

Through trajectories of Spanish women scientists who went abroad and of some foreigners women who worked in Spain, particularly in Physics, Chemistry and Biology, it is highlighted, first, the welcoming attitude of the Spanish republican institutions, and secondly, the benefits obtained by women from the international women's organizations engaged in promoting scientific training for women.

Between 1907 and 1936, at least 30 women enjoyed the opportunity to broaden their studies or research abroad. Two came to Spain from other countries, while 28 Spaniards received scholarships to the United States (12), Germany (8), France (6), England (4), Switzerland (3), Belgium (3), Austria (1), Denmark (1) and Italy (1).

This support was crucial for the inclusion of Spanish women in the emerging scientific community in Spain, unfortunately miscarried by the wars in Spain and Europe.

Introduction: the relationship between US women and Spanish women

In September 1921, a newspaper published in New York and written in Spanish brought the following news: "A brilliant group of Spanish ladies will join the American university course". What had happened?

What had happened was that four Spanish women who had received a scholarship in order to specialize in various scientific matters had come to the United States. Their names were: Carmen Castilla, Concepción Lazarraga, María Luisa Cañomeras and Loreto Tapia. Their scholarships for the course 1921-1922 were the first to be granted under the agreement signed by the Spanish Ministry of Education and Martha Carey Thomas, who was acting on behalf of the American Association of University Women (AAUW).

Carmen Castilla went to Smith College for further studies in Science education; Conception Lazarraga to Barnard College for studies in Chemistry as did Mª Luisa Cañomeras; and Loreto Tapia went to Bryn Mawr. Next to them were traveling Herminia Rodriguez (graduate in Pharmacy and Chemistry) and Nieves González Barrios (Ph.D. in Medicine from the University of Salamanca), who was intended to study bacteriology and childhood diseases in a prestigious clinic, supported by a pension from the JAE.

M. Carey Thomas, recognized as one of the most important leaders for education of women in the United States, was the president of Bryn Mawr College in Philadelphia (Pennsylvania, USA) and a member of the International Relations Committee of the Association of Collegiate Alumnae (ACA), organization born in 1881 for advancing educational and professional opportunities for women in the USA and in the rest of the countries. In 1919, the ACA grouped more than ten thousand scholars, among which were included presidents, deans, directors and professors from all U.S. states and Canada. The ACA changed its name to AAUW in 1921.

The first connection with American women's associations had begun with the establishment of the "International Institute for Girls in Spain" (IIGS), created in 1877 as a girls' school in Santander, Spain, which moved in 1903 to Madrid, where it was known as the "International Institute" or "Boston Institute".

The American-Spanish relation intensified with the foundation of the *Residence for Ladies* (the "Residencia de Señoritas"), an institution for women students founded in Madrid, in 1915, directed by Maria de Maeztu. The Residence and the IIGS were physically close and shared its main educational orientations. This closeness led to set exchanges with the American women's college who supported the IIGS.

Some clues on the situation of women in Spain at the beginning of the 20th century

The Spanish economic reality of the late nineteenth and early twentieth century was characterized by the predominance of a rural society, low levels of industrialization and a structural weakness of the middle classes. At the ideological level, the exorbitant influence of the Catholic religious ideas in Spanish society was notorious, and at the political level, there was a sharp polarization between conservative and liberal positions. The improperly called universal suffrage, widespread voting for men, was reached in Spain in 1868 and will become truly universal for men and women in the Second Republic in 1931.

The Spanish universities and high schools were first open to women in 1868, as part of the political revolution which occurred in September that year, which would imply a series of liberalizing laws, among others, that of *Freedom of Education*, that of *Freedom of Religion* and the *Universal Male suffrage*. In those years, Spanish law was among the pioneers in recognizing the right of women to receive higher education. Later, however, conservative governments backed down to size.

Obtaining degrees and the practice of the profession were two difficulties for the first women scholars. In our country, the professions will be one of the problems. Concepción Arenal, one of the most enlightened voices of the moment, in her book *The Woman of the future*, wrote about the contradiction posed by the fact that in Spain a woman could be Queen and tobacconist, but she could not practice any intermediate profession.

In 1900, 66% of Spanish women and 45.3% of Spanish men were illiterate. They lacked the means to pay tuition fees, centred as they were on tasks of survival. In those days the *Normal Schools for Teachers* were the most popular channel for women to achieve an education and to exercise a profession.

In Spain, the law that allowed women the free access to university was passed in 1910. That year, 21 women were studying at Spanish university among 15.000 men, what then meant a short 0.1%.

Liberal groups and Krausists, through the *Free Institution of Teaching* (ILE in its Spanish acronym) and the *School Institute* ("Instituto Escuela") constituted the nucleus in favour of changing the traditional conception of education for women.

Institutional mechanisms and Networks from which women benefited

The institutional mechanisms and networks from which some Spanish and international women scientists benefited (obtaining support for travelling and studying abroad), between 1907 and 1936, can be classified in three categories:

- Institutional mechanisms: The scientific politics of JAE (1907-1936)
- Networks of women's organizations
  - Fellowships given by the ACA and the International Association of University Women (IAUW)

    - The interchange established through the relationship between the International Institute for Girls in Spain and the Residence for Ladies (Residencia de Srtas.)
- Political international networks
    - Zionists networks
    - Personal and familiar networks

1. Institutional mechanisms: The scientific politics of JAE

Since 1907, the JAE was the institution responsible for articulating the scientific policy in Spain. Particularly, they were responsible of everything related to scholarships for study abroad. From the outset it established a systematic program of sending researchers, faculty and graduates abroad. The Founding Act of the JAE affirms that to promote scientific research, connection with the "scientific and educational movement of the most cultured nations"[1] is essential. And to achieve this purpose was imperative to promote and support a fellowships program for stays abroad.

The policy of the JAE was characterized by the following features: an open mind without rigidities nor bureaucratic red tape, a special attention to people with professional prestige, a prioritization of the issues that met the needs of the country, support to the current research topics and special interest, a respect for the reports of expert committees, the continuing support for the renewal of teaching and flexibility to adapt to increases and decreases in budget and to the political changes occurred over the years.[2] To these features it could be added a positive sensitivity for to not discriminate against women in the provision of fellowships.

The JAE was integrated by men (only a woman, Maria de Maeztu, belonged to it) of the Free Institution of Education, liberal thinkers as Giner, Cossio, Luis de Zulueta or Castillejo. They maintained a favourable disposition towards the promotion of women in science. Example of this progressive spirit is that throughout its existence (1907-1938) the JAE was increasing the rate of fellowships awarded to women (see table 1), from a 4% in the 1910s decade to a 13% in the 1930's.

Table 1: Number of fellowships for women, conceded by the JAE[3].

Period	**Nº of fellowships for women**	**Total number of fellowships**	**% Fellowships for Women/ Total**
1908-1919	27	645	4
1920-1929	41	539	8
1930-1934	53	410	13

In the first third of the 20th century, the number of women who received a fellowship from JAE, for scientific studies abroad, was 18. The fellowships received by those women were 20[4].

The name of women scientists, their degrees, the subject of study and place of destination, of those who received a fellowship in the fields of Physics and Chemistry are included in table 2. The same information for the field of Natural Sciences is included in table 3. The same information for the field of Medicine is included in table 4.

Luisa BELTRÁN LOGROÑO	Graduated in Pharmacy	SWITZERLAND, 1934 – Food analysis

The figures of women who went abroad for scientific training are higher if we consider other ways of obtaining fellowships that benefited women and are specified below.

2. Networks of women's organization

In the first third of the 20th century, in Spain, women also benefited of the fellowships given by women's associations, which established networks for supporting high female education around the world.

Two were the ways by which women could obtain the necessary support for implementing their careers:

- Fellowships given by the ACA-AAUW and the International Association of University Women (IAUW).
- The interchange established through the relationship between the *International Institute for Girls in Spain* and the *Residence for Ladies* ("Residencia de Señoritas")

As it has been said before, on behalf of the AAUW, Martha Carey Thomas, visited Madrid and offered the Spanish government the possibility of exchanges for young post-graduated women. An agreement was put in place to facilitate scientific studies abroad for many Spanish women. These scholarships were aimed at those women student who, having studied at university, wished to pursue specialized courses in American universities. The total amount covered the costs of accommodation and teaching but not travel expenses. At the time this proposal was being studied, an exchange program already existed for fellows; it came out of the relationship between the *Residence for Ladies* and the *International Institute for Girls*.

This mechanism explains the significant growth of women traveling to the USA. The number of women who received a fellowship from these networks was 12. The fellowships received by those women were 14[5].

The name of women scientists, their degrees, their subject of study and place of destination, of those who received a fellowship this way, in the fields of Physics, Chemistry, Natural Sciences and Medicine, in the 1920s decade are included in table 5. The same, in the 1920s/1930s decade are included in table 6. The same, in the decade of 1930s are included in table 7.

[5] The data included in tables 5, 6 and 7 were taken from: Carmen MAGALLON (2004) *Pioneras españolas en las ciencias*, Madrid, CSIC, and from the mentioned Archive of the JAE.

3. Political international networks

We found that some women got help for their studies or careers in different countries due to the influential situation of their families in the political context of the time. Example of this would be the following:

3.1. Zionists networks

It is the case of Dina Scheinkin (1898-1933). Born in Odessa (Ukraine), she later studied Natural Sciences in Madrid. She was the daughter of a Russian-born Zionist activist who in 1906 emigrated to Israel / Palestine. He was expelled from Israel and emigrated to the USA, while his wife and daughter settled in Madrid. In the science faculty, Dina contacted Antonio de Zulueta and the Natural Sciences Museum, where she later served as assistant. Between 1920 and 1922, she taught natural history in the mentioned "Instituto-Escuela". The only award she won in Spain was that of the JAE to take a course in the *Laboratory of Marine Biology* in La Coruña in the summer of 1920. However, from October 1923 to October 1924 she was in Berlin at Kaiser Wilhelm Gesellschaft as a guest of Richard Goldschmidt, according to research by Vogt (2008)[6]. Later, in 1932-1933 Dina Scheinkin was co-director, along with J. Carmin, in *The Independent Biological Laboratory* in Tel-Aviv (founded in 1928 and active until the fifties). It should be noted that Dina's father, Menahem Sheinkin, was one of the founders and early inhabitants of Tel-Aviv.

3.2. Personal and familiar networks

It is the case of Carmen Gómez-Moreno (1914-2008) who was the daughter of archaeologist Manuel Gómez-Moreno and Maria Elena Rodríguez-Bolívar. She belonged to one of the most influential families in Granada and Spanish society, related to Giner de los Ríos, Ferrant, Menéndez-Pidal, etc. She studied at the "Instituto-Escuela" and then entered the university and graduated in Natural Sciences in 1936. After the war and post-war hiatus, 1950 was a turning point in her life and her career, moving to America to study art history. She left a promising career as a scientist to follow her father's footsteps. Receiving an M.A. from Harvard University, she began her curatorial career at the Metropolitan Museum of Art in New York (MMA) in 1956. As she told her friends, she left Spain under Franco, as there really were no opportunities in Spain for her. She was curator of medieval art, and was the author of a book on Spanish painting and essays on treasures such as The Apse from San Martín at Fuentidueña. She was responsible for the monumental task of transferring the apse from the citadel church dedicated to San Martín at Fuentidueña in the vicinity of Segovia (a loan from the Spanish government arranged by her fathers) to New York, where it was installed at The Cloisters.

Other outstanding cases

In other publications[7] we have written about some of the women scientists included in the tables, those who worked on the research teams in Spain in those years and who contributed to scientific advancement in their fields. Here we will point out some of the less known and equally remarkable.

1. Käte Pariser (1893-1953), who came to Spain with a fellowship from the IAUW

She began his experimental work in genetics at the *Kaiser Wilhelm Institut für Biologie* in Berlin with Richard Goldschmidt, completing his doctorate in 1927. With the support of Zulueta, Goldschmidt and the German scientist Hilde Mangold, Pariser asked a scholarship for foreigners to the Madrid *Association of University Women* (a member of the *International Federation of University Women*). These scholarships were granted with funding from the Cultural Relations Board, Ministry of State. Before knowing the answer, she had to leave Germany because of the Nazi seizure of power. After staying three years in Madrid (1933-36), when the Spanish Civil War started she flew to Tel-Aviv. As far as we know, she then migrated to Australia and probably returned to Germany by the 1950s.

2. Jimena Fernández de la Vega (1895-1984)

One of the early women to graduate in Medicine in Spain (1919), she was the introductor of the genetic theories and techniques in Spanish medicine. She learned them in Germany and other European countries as a scholarship holder, working with scientists such Friedrich Kraus, Theodor Brugsh, Erwin Baur and Eugen Fisher (Berlin), Hermann Poll (Hamburg), Julius Baur (Vienna) and Nicola Pende (Geneva). In Spain she collaborated with outstanding physicians and

physiologists such R. Novoa Santos, G. Pittaluga and G. Marañón. In 1933, she was designated director of Genetics and Constitution department at Medicine Faculty in Madrid.

3. Margarita Comas Camps (1892-1973)

She was the first daughter of a liberal teacher, who participated on the "Institución Libre de Enseñanza". In 1915 she started as a Physics-Chemistry and Natural Sciences teacher at the *Normal School for Teachers* in Santander. In 1920 she was granted by the JAE for staying a year in the Belford College for Women in London (England), in order to study sciences teaching methodology. In 1921 she entered Natural Sciences faculty, although she had to work simultaneously, and graduated in 1925 with the best marks. Between 1926 and 1928 she stayed in Paris making her doctoral research. The JAE gave her a leave of absence (as a professor in the *Normal School for Teachers s*he was a civil servant and she needed a special permit for travelling). From 1932 on, she worked at the Pedagogy department of Barcelona University. In 1937, during the Spanish Civil War, Margarita Comas went to England in order to take care of refugee children, and, because of political persecution, she and her husband had to go into exile. She got an appointment as a teacher of biology at Darlington Hall School (Devon), living in England until she died in Exeter.

Conclusions

Our study underlines the fact that, in the historical period of this study, women participated in international exchange responsible for the science improvement in our country. Women participated in these exchanges in significant percentages, although limited by the small number of women who had access to higher education (Normal Schools for teachers, and Universities). Social extraction of these women was characterized, not by wealth but by the proximity to liberal environments and the fact of belonging to families of Spanish and international intellectual elite.

On the other hand, many of these women entered university after having completed studies in Normal Schools for Teachers, and they were mostly devoted to teaching duties. That explains the late age at which many had access to scholarships, compared with men, and also why they did not obtain the most prestigious international destinations. For example, any doctors in Natural Sciences had a scholarship to the Naples Zoological Station – a privilege that American women enjoyed thanks to their associations, as happened to Nettie Stevens, Marcela Boveri, and many others, while in our country this privilege was limited to a few men.

They were few women who could later engage in scientific research in Spanish institutions (some did, as Dorotea Barnés or Jenara Vicenta Arnal Yarza at the *National Institute of Physics and Chemistry*). Family support or friendship environment provided some others access to jobs *despite their gender*. This was the case of Jimena Fernandez de la Vega, appointed in 1933 director of the "Genetics Service" established at the Faculty of Medicine in Madrid, an institution that failed to develop as research centre: just after the death of her mentor, Nóvoa Santos, it became a "Seminar for the Study of Genetics", theoretical, instead of becoming the experimental laboratory that was originally planned.

Later most scholar women were devoted to teaching in the Normal Schools and High Schools. This had a positive impact however, because their preparation helped to improve the scientific training of the next generation of women students. Also, exchanges with American colleges and visits to other countries increased greatly the handling of different languages, especially English –an improvement that unfortunately did not continue in subsequent periods.

Many were the benefits obtained by the fellowships to women, among them, the results of its own investigations, the contacts they established with research centres, the exchange of publications, techniques and materials, and in some cases, the introduction in Spain of the latest developments in their fields (for example, Jimena Fernández de la Vega or Margarita Comas in genetics and Dorotea Barnes, in Raman Spectroscopy).

This could not have been possible without the support and encouragement offered to our country by university women associations. The wisdom of those women in creating a wide net for promotion of other women, the help and cooperation smoothed the way for improving the gender balance in science, which not only resulted in significant changes in the social organization of science, but also in its advancement.

KNOWLEDGE AND TECHNOLOGY
IN THE MEDITERRANEAN BASIN

Abstract

In mid-August 1877 Alexander Graham Bell started what he had planned as a short stay in Great Britain but finally lasted until the end of October of the following year. Despite general scientific recognition and continuous engagements to present his invention, at the beginning of this period he was eager to work personally on the more commercial aspects of its introduction in Europe but, increasingly disenchanted with the difficulties encountered by his patents, he ended up leaving business completely in the hands of the concessionaries.

To the author's knowledge the French case has received little attention. Based, among other sources, on family letters made available on the internet by the Library of Congress, this communication will show that Bell travelled at least three times to Paris from London, each trip corresponding to a different state of his affairs and attitude towards them. This research will also serve to pinpoint three initial phases in the history of the telephone in France: the heralding work of Alfred Niaudet and the Maison Bréguet; their efforts, together with the concessionaire, Cornelius Roosevelt, to fight the imitators and develop more powerful transmitters; and finally the appearance of Bell's friend Frederic Allen Gower which would eventually lead to the formation of the first telephone company.

After months of improvements and public exhibitions of his invention in the United States, Alexander Graham Bell got married on July 11, 1877, in Cambridge, Massachusetts. His bride, Mabel, was a daughter of Gardiner Green Hubbard, a long-time sponsor of his work, who only two days before had been elected trustee of the newly-established Bell Telephone Company. On August 4 the couple sailed for England, carrying with them a supply of telephones on what was intended to be a short honeymoon trip including some promotional activities, but Mabel's early pregnancy made a longer stay advisable. They were not back in America –with their baby daughter– until November 10, 1878.

During this time the Bell's settled in London, but the inventor's lecturing and business engagements took him to many places in Great Britain and Ireland, as well as –so it turned out– to Paris, on at least three occasions. No mention of the trips to France has been found in the literature, not even in Bruce's biography, which gives the most complete coverage of the period[1]. What follows is a brief account of these trips, relying heavily on the information contained in the family letters made available on the internet by the U. S. Library of Congress. An attempt is made to put such travels in the context where they belong, that is, the early history of the telephone in France.

The first trip: trying out a business role

Telephones made by his company preceded Bell in France. Correspondence from late October and early November indicates that his father-in-law had sent a box of them to one Le Gay, at 3, rue Scribe in Paris, intended for "the Scandinavian and other agencies"[2]. Besides, Bell himself had in London given two such telephones to Alfred Niaudet, "one of the firm of Breguet Bros. of Paris, the best electricians in France", for exhibition purposes[3]. Louis Breguet, the master of the renowned factory, showed these telephones to his colleagues of the Academie des Sciences during its session of October 29[4], and Niaudet took them to the Société Française de Physique on November 2[5], where he announced that Bell "had promised him formally to go soon to Paris and speak in a scientific meeting"[6]. Niaudet also demonstrated the telephone at the École Polytechnique at the opening of Jules Jamin's physics course[7], and, on December 7, at the Société des Ingénieurs Civils[8].

At the time of his marriage Bell had made his father-in-law the sole trustee of his patent rights in the five European countries (Britain, France, Belgium, Germany and Austria) where he had filed applications or was about to do so[9]. Once in Britain, where an agent had already been appointed, he grew increasingly concerned about the development of the telephone business on the continent, partly because he thought that if Hubbard placed it under his supervision he could obtain extra income in the face of rising family expenditures. Mabel was certainly of the same opinion, as shown in a letter of October 25 to her mother-in-law, Eliza Symonds Bell:

> *"Then there are his patents in France, Belgium, Germany, Austria and Italy. All except the last one in the control of my father as my trustee, but of course when he is so far away and has so much to occupy him at home, he cannot manage the business so well as some one here could…"*

Three days later Bell referred the matter to Hubbard:

> *"It has struck me that it might be possible to make the continental patents benefit us now as well as hereafter – if some arrangement could be made – to appoint me General Agent for these Patents*

---

[1] Bruce, Robert V., *Bell: Alexander Graham Bell and the Conquest of Solitude*, Cornell University Press, 1990. No reference to the trips is found either in Aulas, Pierre, *Les origins du téléphone en France (1876-1914)*, Paris, Association pour le développement de l'histoire économique, 1999.

[2] Hubbard to Bell, November 2, 1877. This "Chal Le Gay", for whom Hubbard had asked Bell on November 13 to send fifty more devices, "to furnish several parties with telephones on trial", may be the Paris merchant Charles Le Gay, mentioned, in relation to wine exports to the U. S., in the book *Franco-American Commerce / Statements and Arguments in Behalf of American Industries Against the Proposed Franco-American Commercial Treaty*, San Francisco, 1879, p. 133. He may also be the same person whose death was reported by *The New York Times*, January 10, 1909: "Paris. Jan. 9.– Charles Le Gay, a former American, who had lived in Paris for some years, died here to-day".

[3] Bell to Hubbard, October 28 and November 1, 1877. In the former, Bell writes: "I have sent telep[hones] to Paris to be exhibited", and in the latter he specifies: "I have given Mr. Niaudet telephones to exhibit in France". This is in agreement with Niaudet's statement in his December 7 presentation to the Société des Ingénieurs Civils: "Une circonstance fortuite m'a conduit à Londres le mois dernier [an error in the transcription or the speaker's own confusion: this had happened in October, not in November]. Je fus mis en rapport avec l'inventeur. Je lui proposait de faire connaître son invention en France. Il me confia les deux premiers téléphones qui aient touché le continent européen, et que voici". Bell improperly calls Maison Breguet "Breguet Brothers". The current owner was Louis François Clément Breguet, assisted by his son Antoine and his nephew Alfred Niaudet.

[5] *La Nature*, November 10, 1877, pp. 383-384.

[6] Also *La Nature*, September 29, 1877, wrote the following when it published the translation of William H. Preece's report on the telephone at the Plymouth meeting of the British Association (pp. 274-276): "... les progrès qu'elle [l'invention du téléphone] fait de jour en jour nous obligent à y revenir aujourd'hui. M. Bell est du reste attendu à Paris, et tout le monde pourrra bientôt apprécier sa découverte".

[7] "Revue des Sciences" by Henri de Parville, *feuilleton* of *Journal des Débats*, November 29, 1877.

[8] *Mémoires et compte rendu des travaux de la Société des Ingénieurs Civils*, vol. 30, Paris, 1877, pp. 839-849.

[9] British patent 4,765 of December 9, 1876. French patent 119,626 of July 25, 1877. Bell may have applied for the other patents, which the author has not located, at the same time as the French patent.

> *until the organization of companies there – with a commission [...] It is necessary to do something here at once on the continental if I had power in the matter could negotiate I think profitably".*

Such was the situation when Bell made his first trip to Paris. On the evening of November 21, just arrived from London, he sat down in his room at the Hôtel Wagram to write a letter to his wife. He had scarcely had time to tell her about the rough seas he had encountered between Folkstone and Boulogne, when at eight o'clock he was interrupted by Niaudet's visit. After an interview lasting two and a half hours he resumed his letter: Niaudet would take care of translating and publishing in France a non-specified lecture by Bell[10]. Next day Bell was to see Le Gay and another dealer called Aymler[11], and also the chief of the French Telegraphs, Pierret, and the Minister of War, to whom he intended to give telephones for experimental purposes.

Concerning this trip, there is also an undated letter of Mabel to her husband, which she must have written on the same day of his departure, just after receiving a telegram of his from Folkstone Harbour asking, among other things, for a letter from Aymler that he had probably forgotten to take along with him. Mabel tells him encouragingly that the more she thinks about it, the more important it seems to her that he is in Paris[12].

No other documents have been found that allow the duration of Bell's stay in Paris to be established. This was presumably short, and –despite his alleged promise to Niaudet of addressing the scientific community– without any public engagements, judging from the silence of the great Parisian press. Nevertheless, some of the five papers reviewed, *Le Figaro*, *La Presse*, *Le Temps*, *Le Gaulois* and *Journal des Débats*, contained news about the telephone on those dates. In particular, they reported on a meeting of Louis Breguet with journalists on November 28, at which he showed the devices and said that he had tried them successfully between Paris and Mantes-la-Jolie, 58 km apart, and intended to repeat the experiment with Nancy[13]. Surprisingly enough, on December 14 *Le Temps* published a long article about the telephone under the heading "Chronique", written in the first person but unsigned, the last paragraph of which contains an intriguing reference to what may have been Bell's impression of his trip:

> *"It seems that to begin with, M. Graham Bell has not been delighted with the reception he has met with in France; he could have been taken for an eccentric; this is the excuse that routine usually opposes to progress"[14].*

The second trip: helping the business of others

Hubbard was not responsive to Bell's demands for a more active role in managing the introduction of the telephone in the countries where his son-in-law had given him control of the patent rights. In the case of France, he decided of his own accord to appoint Cornelius Roosevelt as concessionaire. A first cousin of the future U. S. president Theodore Roosevelt, he belonged to a wealthy New York family and had returned to America after the failure of his initiatives to introduce private telegraphy into France –the so-called district telegraph or "telegraphe de quartier"[15]. His brother Hilborne Lewis, who was one of Hubbard's partners in the telephone business, may have recommended him in view of his knowledge of the French language and customs[16]. On December 1, Cornelius sailed back to France with a letter of presentation for Bell.

---

[10] Probably the one he had given to the Society of Telegraph Engineers on October 31. *La Nature* published the translation, "presque en totalité", in two parts, on April 27 and May 4, 1878, pp. 337-342 and 355-359, under the title "L'histoire du téléphone racontée par son inventeur". In England it appeared in book form: "The Telephone. A Lecture Entitled Researches in Electric Telephony, by Professor Alexander Graham Bell, delivered before the Society of Telegraph Engineers, October 31st, 1877. Published by the Society [...] London [...] New York [...]1878. "

[11] Perhaps John Aylmer, civil engineer, at 4, rue de Naples, who in 1877 was honorary secretary in France of the Society of Telegraph Engineers, London, and in 1881 was appointed secretary of the British commission for the International Electrical Exhibition to be held in Paris that year.

[12] There is further evidence of the letter corresponding to this trip, despite a misleading abbreviation that looks like "Oct" in the place where Mabel usually indicates not the month but the day of the week. In fact, she tells his husband that the notes of his "Glasgow conference" have arrived, in probable reference to one of the several talks he gave there between November 8 and 14 (see the letter dated November 12 from Mabel to her mother-in-law). On the other hand, the letter was sent from "Jermyn St.", which was the Bells' London address only until the end of November (see the letter dated December 2 from Mabel to her mother-in-law).

[13] *Le Figaro*, November 29, 1877, referenced by *Le Temps* of the following day.

[14] "Il paraît que M. Graham Bell n'a pas été tout d'abord ravi de l'accueil qui lui a été fait en France; on l'aurait pris pour un excentrique; c'est la défaite que la routine oppose d'ordinaire au progress".

[15] He was granted French patent 117,492 for a "télégraphe de quartier". He applied on March 13, 1877. (*Bulletin des lois de la République Française*, 1878, first semester, p. 769).

[16] Hilborne Lewis Roosevelt, younger than Cornelius by two years, died prematurely in 1888 at the age of 37. He has gone down in history as the remarkable builder of the first electrically-actuated, large organs in the United States. He also patented in this country some telephonic devices and was one of the founders of the Bell Company of New York.

In the letter, dated November 29, Hubbard highly commended its bearer. The following day he wrote privately to Bell: "I think you will like Mr. Roosevelt very much, and that the arrangement will please you. It is made to depend on your approval". On December 11 he insisted only on the first part of the message: "I trust you will be pleased with Mr. Roosevelt", adding: "He has not as much business experience as some, but he is thoroughly honest and is better capable of organizing a company for France than anyone we could send you". No indication has been found that Bell dared to disagree openly with Hubbard in this matter, but he certainly took his time to meet Roosevelt. It seems this did not happen until a new trip to Paris, where he probably arrived on Saturday, January 19, 1878, this time after crossing the English Channel from Dover to Calais. Only five days later he was back in London, according to a letter dated January 25 from his wife to her mother-in-law, which gives valuable details of his movements[17]:

> *"He has had an interview with the best Parisian lawyers whom Mr. Roosevelt has employed to conduct a prosecution against a firm who are infringing Alec's patents. They said at first that the patent was not worth anything because it had been applied for too late, but Alec succeeded in convincing them that the case was not so hopeless as they had thought and they will begin proceedings at once. Still it will take two years to prove whether the patent is valid or not, and the infringers will probably go on manufacturing – but the prosecution will deter others who were just about to begin to manufacture, and in two years Mr. Roosevelt will have time to establish himself and do a good business even if the patent fails. The French Government recognize Alec and that is a very great thing. Mr. Roosevelt, who some time ago spent long months and large sums of money in the vain effort to get government permission to build private lines and to form a District Telegraph Co. in Paris, says Alec accomplished in half an hour what no one else could do, namely get Mr. Perret, Under Minister of Telegraphs, to offer to build at government expense any number of private lines for telephones, and to give him every facility for trying the telephone on all government lines. Mr. Roosevelt says it quite took his breath away. The Government is going to erect a telephone line from Paris to Versailles, 20 miles, and at Alec's request, began the very next day to put up a line for Mr. Roosevelt. Alec called on M. Léon Say, Minister of Finance, and the Ministers of War and Navy. On Mr. Roosevelt's telling Mr. Léon Say that the empress Eugenie had requested Alec to show her the telephone, he agreed with Mr. Roosevelt in thinking it could be well for Marshall Mac Mahon to see it first, and he will ask him to appoint a day".*

Bell had certainly felt obliged to react to distress calls coming from France. His instrument was simple and easy to copy, so that at least one Paris merchant had managed to have telephones ready for sale on Christmas. This was Guillaume Walcker, the owner of Bazar du Voyage, a large department store at place de l'Opéra[18]. Roosevelt immediately began advertising in the press that Maison Breguet had been chosen as the exclusive manufacturer and warning unlicensed makers that they would be prosecuted[19]. But to no avail. According to one source, Walcker "made and sold some two or three thousand" telephones "in defiance of Bell's patents"[20].

This time Bell's stay in Paris resulted in a few paid lines in at least two of the city newspapers. The reports which have been found are alike, although they disagree on the dates, and mention telephone demonstrations at Say's residence as well as a dinner offered to Bell by his concessionaire, attended by "several French *savants*"[21]. It is surprising that Mabel, always so eager to praise Bell's feats to his mother, did not refer to this meeting in the letter quoted above.

---

[17] From the Hôtel Wagram Bell wrote his wife a relaxed, undated letter bearing only the indication "Saturday", which contains a funny description of his fellow travellers in the train from London to Dover. He also tells her that his first move in Paris has been to send a note informing Roosevelt of his arrival. According to Mabel's letter of January 25, Bell had been away for six days and returned on the 24th, which is consistent with his having left on the 18th and arriving in Paris on the 19th, a Saturday. An earlier second trip to Paris should be discarded, among other reasons because Bell's mother wrote him and Mabel on February 25, telling them that Mrs. Hubbard had sent her some of their letters: "therefore we are pretty well up to your doings, till you departed a second time for Paris, from whence we hope you have before this returned". It is likely that two undated letters from Mabel to her husband correspond to this trip. These letters may have been sent on January 20 and 23 and begin, respectively, "I imagine you hard at work with Mr. Roosevelt..." and "I will only write a short note this time..."

[18] See news of these telephones (p. 3) and ad (p. 4) on *Le Figaro*, December 24, 1877. The Bazar du Voyage in Turgan, Julien, *Les grandes usines*, vol. XIV, Paris, 1882.

[19] See, for instance, *Le Figaro*, December 25, 1877, *Le Temps*, December 30, 1877 and *Le Gaulois*, January 27, 1878. The ad on *Le Figaro* was probably prompted by the publicity of Walcker's telephone that the paper carried the day before.

[20] George Lewis Gower, brother of Frederick, the telephone pioneer, in a letter to the *Chicago Daily Tribune*, September 3, 1879.

[21] *Le Figaro*, January 24, 1877, in the "Petite gazette" section, and *Le Gaulois* of the following day.

The last trip: receiving some scientific rewards

Maison Breguet and Niaudet counterattacked the forgers by developing modified/improved versions of the telephone. They were shown at the Universal Exhibition, which opened in Paris on May 1, 1878. Besides describing changes in the construction of the conventional apparatus, the journals reported on a “watch” or “snuff-box” pocket model, a modified box type for long lines and a fairly simple arrangement to call the correspondent station by singing into the telephone[22]. In June, Bell’s former assistant Frederick Allen Gower arrived from England[23], joined Roosevelt and also began to work on the telephone, his first achievement probably being a further modification of the box model which he patented with his new partner in September[24].

That same Summer, on the occasion of the Universal Exhibition, Roosevelt and Gower were very worried about the interest aroused in Paris by the telephonic work of Thomas Alva Edison and other American inventors, such as Elisha Gray and George May Phelps. On September 7, after Roosevelt had tried unsuccessfully to see Bell in London, they jointly wrote him a letter asking him to stand by for “an overwhelming blow”: “a grand exhibition” of his improved telephones, which would be demonstrated between Paris and Versailles[25]. However, Bell did not go. His mood in those days is clearly reflected in a letter that he sent to his wife on September 9 from Greenock, Scotland, where for a short time he was happily back to teaching speech to the deaf:

> *“Of one thing I am quite determined and that is to waste no more time and money upon the telephone. If I am to give away any more of my time – it must be for the object that is nearest my heart. If it is absolutely necessary for Mr. Roosevelt’s interests that I should go to Paris he must pay my expenses from Greenock to Paris and back – and remunerate me for my time – otherwise I will not dream of stirring. I have been twice to Paris for Mr. Roosevelt at considerable expense and inconvenience to myself and neither time was my presence absolutely necessary although he led me to believe so. I don’t intend to go the third time. I am sick of the telephone and have done with it for altogether – excepting as a play-thing to amuse my leisure moments”.*

Considering the fact that when Bell made his first trip to Paris in November 1877, Roosevelt had not yet appeared on the scene, his words suggest that he returned to the city in the interest of the concessionaire after his first interview with him in January 1878. No family correspondence or press reports referring to this third trip have been found[26], but a fourth one is well documented. This time Bell’s priority in the invention of the telephone was at stake, as Hubbard had bluntly expressed in a letter of September 26, referring to the Universal Exhibition:

---

[22] “French telephones at the Paris Exhibition”, *Engineering*, June 21, 1878, p. 500. See also “Exposition Universelle. Matériel et procedés de la téléphonie.– Téléphones et accesoires de la téléphonie (Société Anonyme des téléphones Bell, 1 rue de la Bourse, Paris)”, *Les Mondes*, May-August 1878, pp. 368-373. Besides the mention of the apparently new company (located at the concessionaire’s address), the article contains interesting information: “... after the appearance of the American instrument, we have received many questions, all with the same purpose: to find out how to procure the best telephones. Unfortunately we have remained for a long time undecided about the answer, because of the many forgeries of which the apparatus has been the object. Lastly, at the Exhibition, we were going through one of the rooms dedicated to telegraphy when our attention was attracted by a telephonic showcase, on top of which one could read ‘Sole concessionaire of the French patents’. We wanted to be sure of the value of this title and with the greatest satisfaction we attended demonstrations on the premises of the concessionaire himself, who asked us to examine his patents”.

[23] Frederick Allen Gower (born Sedgwick, Maine, July 25, 1851 – died somewhere in the English Channel, July 18, 1885) was a journalist with *The Providence Evening Press* of Providence, Rhode Island, when he met Bell on the occasion of his telephone demonstration at Salem, Massachusetts, on February 23, 1877. Bell became very fond of him “both as a friend and a business man”, as he wrote in those days, and made him his assistant in charge of his telephonic shows. At the start of the Bell Telephone Company, Gower was appointed general agent for New England (excepting the city of Boston), and after Bell’s departure he was also given the exclusive right to lecture on the invention in the United States, for which purpose he developed a so-called “telephone harp”, a generator of electric signals that could be transmitted over the line and produce the sound of musical notes in the telephone receiver. He rejoined Bell in England in April 1878, and during the following month took the opportunity to show his instrument at the Royal Society and use it to illustrate James Clerk Maxwell’s Cambridge University lecture on the telephone. After going to France in June to help Roosevelt, his career developed quickly, his “Gower-Bell” telephones being sold all over the world. He was a very rich man when in 1881 he became interested in controlling balloons for aerial warfare, an endeavour that cost him his life in a flight from Cherbourg.

[24] French patent 126,511, filed September 12, 1878, “Perfectionnements dans le téléphone à boîte” (*Bulletin des lois...* 1879, second semester, p. 670). The improvement is mentioned in Du Moncel, Th., *Le téléphone, le microphone et le phonographe*, 1st. edition, Paris, 1878, pp. 73-74. This pioneering book must have appeared around the end of August, given that the 15th of this month is the latest date referred to in the text, and also that the author presented a copy to the Académie des Sciences at its meeting of September 15.

[25] In the letter, Roosevelt also appealed to Bell’s honour: “The Edison and Gray with Phelps have combined their interests and have made quite a stir here by exhibiting at the Exposition, before the press, etc. They draw a very long bow and to judge from their tone one would imagine that Bell was an impostor and a cheat”.

[26] In the letter of January 25 quoted above, written just after Bell’s return from Paris, Mabel tells her mother-in-law that “he will have to go again in a fortnight”.

"The newspapers in this country have been full of advertisements and notices of the fact that Gold Medals were awarded to Mr. Gray and Mr. Edison and none to you. This advertisement is a great injury to us, and we think it was obtained through fraudulent representations, and that the final award will not be made until the 21st day of October. The Chairman of the jury thinks the invention so great a wonder that it could only have been made by a scientist and electrician. Gray's agents have represented that Gray was a scientist and electrician, that you were not; and that you stole the invention from him. Now we want to have you go at once [to] Paris at our expense, take Gray's letters with you[27], see the Chairman and jury and make your own explanation. That alone will be enough, anyone on a little conversation will see that you know enough to have invented the telephone and that you are both a scientist and electrician. I have also sent by book post, Prescott's book on the telephone which contains Gray's caveat, showing how little he knew, and a copy of your patent to show that it was on hand two weeks before it was filed[28]. Your pecuniary interest in this matter is too great to be neglected, and your honour also is somewhat at stake".

Hubbard's information was not quite correct. What the jury really did was not to deprive Bell of a prize but to put him on the same level of his rivals Gray and Edison by awarding each of them the highest distinction, a "grand medaille", for their telephonic work, which in Edison's case also acknowledged his invention of the phonograph. Besides, Edison was made Chevalier de la Legion d'Honneur[29]. Bell seems to have taken the decision rather sportingly. On October 20 he was again at Hôtel Wagram[30], ready to attend the official state award ceremony the following day, after which he would leave immediately for London and then to Oxford, where the philologist Max Müller had invited him to give a series of lectures on speech, his last scientific commitment before departing for America[31].

The only record found of this trip to Paris is a letter dated October 20 written to Mabel by Adam Scott, one of Bell's fellow travellers[32], and continued on the same sheet of paper by Bell himself. After jokingly reporting on a dinner at Roosevelt's house the previous evening, Scott goes on with important news:

"This morning (Sunday) Alec was introduced to the Count du Moncel, and thoroughly converted him to his views – This is specially important because du Moncel is a great authority here and has allowed himself to be misled by the Gray and Edison party – He is vexed at having thus done Alec injustice, and will set matters right – The second edition of his Book on the Telephone would be published this week, and Alec was just in time to stop the proofs – Du Moncel will correct the views given in the book, and would go further but for the prudence of keeping the actual evidence quiet – He has given Alec a copy of the first edition and Alec is reading it, to become acquainted with its contents, as the proofs of the second edition are to be sent to him tonight..."

Bell, writing after Scott, confirms the good news and adds:

"My arrival here is most fortunate at this time. The Western Union will probably publish extracts from Du Moncel's work – but what a triumph it will be for your father to be able to come down on the Western Union with the second edition!!"

A comparative reading of the first two editions of Du Moncel's *Le téléphone, le microphone et le phonographe* shows clearly the outcome of this episode, which in effect was very favourable to Bell's claims[33].

---

[27] One of the letters Hubbard had in mind was probably that sent by Gray to Bell from Chicago on March 5, 1877, in which he gave him "full credit for the talking feature of the telephone" (see Bruce, op. cit, pp. 220-223).

[28] George Bartlett Prescott's *The Speaking Telephone, Talking Phonograph and Other Novelties*, New York, 1878. Gray's *caveat*, filed, as is well known, after Bell's patent specification on the same day, February 14, 1876, is described in pp. 201-205.

[29] *Le Figaro*, October 27, 1878, reporting on this in "Échos de l'Exposition", wrote that Edison was "the inventor of the phonograph, the telephone and so many other curious discoveries".

[30] Bell must have given some hint of his intentions, because in a short letter dated October 9 Roosevelt told him politely that any day he might fix would suit him, and added with some resentment: "But I must tell you that your visit, aside from the pleasure of seeing you, will be of no great value to us now as the time is past and it is too late. That Gray and Edison have injured your reputation there is no doubt as I have repeatedly written you and even if you can 'effectually demolish their claims' the time has gone by".

[31] See latter of Bell to his mother, October 4, 1878.

[32] Adam Scott, Bell's friend from their childhood, worked for the London Bell telephone agency, which had been entrusted to colonel William H. Reynolds, a Providence cotton broker, in the Summer of 1877. On April 23, 1879 Scott read before the Society of Telegraph Engineers, London, a paper entitled "Recent improvements in Professor Bell's telephone", in which he described a new model devised by Gower (*Journal of the Society of Telegraph Engineers*, 1879, pp. 327-336).

[33] Major changes appear in two places in the second edition: the paragraphs dealing with the question of priority between Gray and Bell in the point "Un coup d'oeil historique" that opens the book (pp. 7-9, corresponding to 8-10 in the first edition), and the whole point "Part de M. Elisha Gray dans l'invention du telephone" (pp. 57-61, corresponding to 56-60 in the first edition).

Further developments

On October 31, 1878, Bell sailed from Liverpool to Quebec, subsequently to face a long period of patent litigation in the U. S. Gower, who later said in an interview that in France Bell's patent "was unfortunately too late to be of legal value"[34], continued working on his friend's invention, publishing the results and filing new patents with Roosevelt, the last one on June 18, 1879. On the 6th the French Government had issued a call for proposals to establish public service telephone networks. Three companies were authorized to operate in Paris, based respectively on the equipment of Gower, Edison and Francis Blake. In late 1880 they merged in one[35]. In that same year Bell returned to Paris to receive the Volta prize (50,000 francs), awarded him by the French Government for the invention of the telephone. In sharp contrast with the visits reviewed in this paper, on this occasion he attended a session of the Académie des Sciences on October 11, toured other relevant institutions and met a number of French scientists and engineers.

Two Roosevelt's ads mentioned in the text.

Avis divers

TÉLÉPHONE-BELL

Les propriétaires du brevet français font savoir qu'ils ont choisi M. Breguet comme seul fabricant pour la France des Téléphones de M. Alexander Graham Bell. Ils poursuivront avec toute la rigueur des lois les contrefacteurs du brevet, fabricants, importateurs, marchands et les acheteurs des objets contrefaits.

On est invité à s'adresser à M. Cornelius Roosevelt, 1, rue de la Bourse, qui est seul concessionnaire pour la France.—Paris, le 24 décemb. 1877.

Le Temps, December 30, 1877.

Tous les **TÉLÉPHONES** véritables du Professeur ALEXANDRE GRAHAM BELL, devront porter la marque de fabrique ci-après.

Les Téléphones non munis de cette marque sont des contrefaçons ou imitations et tous importateurs, fabricants et vendeurs seront poursuivis suivant la loi.

CORNELIUS ROOSEVELT,
seul Concessionnaire des Brevets pour la France.
1, Rue de la Bourse, PARIS.

Le Gaulois, January 27, 1878.

THE RAM-TORTOISE OF HEGETOR OF BYZANTIUM IN THE TREATISE *ON MACHINES* BY ATHENEAUS MECHANICUS. SOME REMARKS ON ITS RECONSTRUCTION

Maurizio GATTO

Abstract

In this paper I present a war-machine, the huge ram-tortoise by Hegetor of Byzantium, whose description is to be found in three ancient sources: Athenaeus Mechanicus, Vitruvius and the Anonymous Byzantine. Because of the general difficulty and obscurity of all these texts, reconstructions of the machine have raised a variety of conflicting interpretations. Basing on a new philological analysis of the text of Athenaeus Mechanicus, which is in my opinion the most reliable source about this machine, I present here a new and more authentic reconstruction.

Introduction

In the ancient literature the name of Hegetor of Byzantium (third century BC), an engineer of military engines, is only found in two works of the second half of the first century BC: Athenaeus Mechanicus' treatise *Περὶ μηχανημάτων* (*On machines*) and in Book X of Vitruvius' *De Architectura* (10.15.2-7). A third mention can be found in the somewhat later essay on poliocertics, written in the tenth century AD by an Anonymous Byzantine, *Παραγγέλματα πολιορκητικά* (*Manual on siegecraft*). However, none of these three works venture into a discussion of Hegetor himself, rather they describe the invention that made him famous: a ram-tortoise of imposing dimensions, known as Hegetor's engine.

A tortoise was a vehicle with wheels entirely covered by planking, which must have resembled, apart from its notably bigger size, the carapace of an animal tortoise. There were smaller and lighter tortoises, which could be carried by hand, like wicker-tortoises, beak-tortoises and many more. But the bigger and more dangerous were undoubtedly the ram-tortoises, which carried a ram used to launch powerful broadsides against the city-walls. Within these models of ram-tortoises, Hegetor's was certainly the most imposing and ambitious in all antiquity.

The descriptions given of this engine by Vitruvius and Athenaeus are surprisingly similar: they follow the same order of topics and rarely does one contain information that the other lacks. On the other hand, the Anonymous Byzantine's description is more autonomous and synthetic. All three descriptions present obscure passages and are therefore difficult to understand. Hence, reconstructing the engine is fraught with complexity. The first attempts in this sense date back to the beginning of indirect tradition of Athenaeus' text. Some copyists wanted to enclose a drawing in the text, but with poor results. Careful philological studies on the text, which have been going on now for almost one and a half centuries, have certainly supplied progressively better representations[1]. However, in spite of these, we still have not obtained a completely satisfying reconstruction.

In my recent edition on Athenaeus Mechanicus' *Περὶ μηχανημάτων*[2] I dealt with all machines he describes and so also with Hegetor's engine. In order to understand it I payed constant attention to the other two sources: Vitruvius and the Anonymous Byzantine. As Athenaeus' text shows itself to be the more complete, I will consider only this treatise here. What I will try to reconstruct is therefore not the engine *tout court*, but the conception of this engine that Athenaeus Mechanicus must have had. Nevertheless it is not unlikely that such reconstruction is actually the most reliable of all.

The results I am about to present derive from a renewed philological work in Athenaeus' text. A different selection of the variants and new interventions on the text have played a determining role in the creation of this new reconstruction. Thus, the reason to set my report like a step-by-step examination of singles passages. The whole description of Hegetor's machine can be divided in four parts: a) the vehicle (i.e. the tortoise, lines 197-223[3]), b) the weapon (i.e the ram, lines 223-236), c) the drawbridge (lines 236-240) and d) mass and performance datas about the whole engine (240-245). In this paper I deal with the first two parts, which are the longest and most complex ones.

The tortoise

First of all Athenaeus describes the supporting base, called έσχάριον[4]. It had a rectangular plan (42x28 cubits) and on the inside a grid network composed by διαπήγματα and περιπήγματα (horizontal and vertical beams) not unlike the grid of the έσχάριον in other tortoises (for instance the filler tortoise). Then he depicts an element that is absent in all other types of tortoise: the σκέλος[5] (otherwise mentioned by Athneaeus just in the description of the Towers of Diades). It must have been a particularly long vertical post, strengthened with a juxtaposition of two timbers fastened together. Almost all scholars have so far imagined that these four σκέλη were placed at the four corners of the έσχάριον. In reality, Athenaeus merely says that they were έπὶ τού έσχάρίον, i.e. on the έσχάριον, without specifying their position. It has to be noted though, that successively (214) another two σκέλη are mentioned, taller than these first two and clearly described as being placed έν μέσω τής χελώνης, i.e. in the central part of the έσχάριον. The position of the mentioned σκέλη will then have to be identified also according to their interaction with the other two. It is therefore better to postpone this question until we will have read the passage concerning the two central σκέλη as well.

After having dealt with the wheels of the engine (201-204), Athenaeus goes back to the surface of the έσχάριον , in order to describe the **colonnade**[6]. Though Athenaeus does not say so expressly, it is clear that these columns were to be

[4] Ath. 197-198.

[5] Τά δέ σκέλη τά έπὶ τού έσχαρίου πηγνύμενα δ συντίθεται καὶ έκαστον έκ β ξύλων συνημ-μένων τὸ μήκος έχόντων πήχεις κδ τὸ δέ πλάτος πηχυαία (198-201).

[6] Κίονες δέ πήγνυνται έπὶ τού έσχαρίου δωδεκαπήχεις, πλάτος μέν έχοντες παλαιστάς γ, πάχος δέ ι δακτύλους. Απέχει δέ άλλος απ΄άλλου κίων παλαιστάς ζ (204-207).

found on the perimeter of the έσχάριον. In order to find their number, Schneider-Schwartz[7] have made a series of calculations which led them to the conclusion that there were 24 of them on each of the long sides and 16 on each of the short sides. Unfortunately their reasoning makes two basic mistakes. Firstly, they compute on each side a number of interspaces equal to the number of columns, whereas the number of interspaces is actually equal to the number of columns minus one (as only one interspace is between two consecutive columns, so that n columns form n-1 intercolumnations). Secondly they suppose that the four σκέλη stand on the four corners of the έσχάριον. For reasons that I will explain later, I am convinced that they were not part of the perimetric colonnade. Thus the calculation must be outlined as follows. Let n_c be the number of columns and n_s the number of the intercolumnations, then $n_s=n_c-1$. Considering that the breadth of each single column is equal to 3 palms and that each interspace stretches for 7 palms, we will get $252=3n_c+7(n_c–1)$, where the first addend represents the sum of the thickness of all the columns expressed in palms, and the second ddend, the complete sum of all the interspaces, always in palms. With $n_c=26$, the sum of the two addends is 253, which is very close to the actual 252. With a good approximation we can therefore assume that the columns on each of the long sides were indeed 26. On each short side, by outlining a similar reasoning we have $168=3n_c+7(n_c–1)$. With $n_c=17$ the sum of the two addends is equal to 163, which is quite close to the actual 168. The 5 palms in excess in that case could have been equitably distributed between the two more lateral interspaces and the two more central (10 dactyls each). Obviously the angular columns are included both in the calculation of the long side, and in that of the short side. So, whilst calculating the total sum of the columns present in the entire perimeter, one must be careful to not count them twice. Therefore if n_{ct} is the total number of all the columns present on the perimeter of the έσχάριον, it will be $n_{ct}=2x26+2x17–2=84$.

On the colonnade laid four architraves on which raised a **roof** made of rafters and a top beam (208-211). Athenaeus says that the architraves placed on them were 3 palms high, which is a half cubit, and the sloping roof was another 8 cubits high. So, considering that the posts were 12 cubits high, we can calculate the high of the whole tortoise as being 12+0,5+8=20,5 cubits. The Tortoise was covered by **planks and rawhide** in order to protect it from fire (211-212). This suggested to Lendle[8] another resemblance with the aforesaid tortoise, not expressly mentioned in the text. He claimed that also on the έσχάριον of Hegetor's tortoise were fixed some protruding rafters (ξύλα ύπερέχοντα). Thus reckoning that Hegetor's engine must also have had a protruding frame around its έσχάριον, where the lower ending of the roof rafters were supposed to be fixed, so creating a covered ringroad around the έσχάριον and in this way enlarging the base of the engine. However, this interpretation by Lendle about the position and the function of the ξύλα ύπερέχοντα is actually incorrect even if applied to the filler tortoise. So, in the case of Hegetor's tortoise he is wrong twice: firstly, because he misinterpreted the structure of the ξύλα ύπερέχοντα itself, and secondly because here such protruding rafters are not even mentioned and there is therefore no reason to believe in their presence. Athenaeus mentions a missile battery (βελοστασία, 213-214) as well, resting on the architraves. Given the presence of the rafters, the planks and its cover, we are forced to imagine that loopholes had been created somewhere slightly above the μέση στέγη to enable the artillerymen to shoot their projectiles out.

After this, Athenaeus talks again about σκέλη[9] (legs). It is clear though that he still cannot talk about those mentioned before (198). In fact four σκέλη were there mentioned, each one 24 cubits high. While here we are talking about only **two σκέλη**, moreover of different dimensions, being ashigh as 30 cubits. The problem of identifying the position and the orientation of the first four had been postponed until now, when the remaining two were mentioned in the treatise, in order to face the problem in its entirety. This is undoubtedly the thorniest question of the whole passage about Hegetor's engine. Luckily, in this second passage about the σκέλη Athenaeus is more generous with information. Firstly, in relation to their position he informs us that the bigger ones were placed έν μέσω τής χελώνης (in the centre of the tortoise) which must clearly mean in the centre of the έσχάριον (base). Secondly, in relation to their orientation, he tells that they were όρθια as well as συμβεβλημένα i.e. vertical and convergent. Although these two Concepts might appear to be contracting each other, we must make an effort to understand what such a term-combination might want to express. The most likely hypothesis is that he wanted to suggest that they were almost vertical, but slightly inclined, so to converge without touching one another. Statically that is the most favourable position[10]. Besides their orientation in space the most surprising thing is their height, which is superior to that of any other element in the engine. We already saw that the four 24-cubit σκέλη exceeded the roof of the tortoise for about 4 cubits but these two central 30-cubits σκέλη exceeded it even for 10 cubits. This means that all the 6 σκέλη passed beyond the covering roof. Certainly they could not be used to keep the position of men or artillery, as they would have been exposed to the enemy's fire. The only possible alternative is to assume that they had some use for the ram. Therefore not only the highest ones, expressly associated to the κριοδόχη, but also the other four must have had the same

[8] Lendle (1975), 51.

[9] Ιστανται δέ καί όπίσω τής κριοδόχης σκέλη β συμβεβλημένα ορθια έν μέσω τής χελώνης, έχοντα τὸ μήκος τριάκοντα πήχεις, τὸ δέ πάχος αυτών πηχυαίον τὸ δέ πλάτος τριπαλαιστιαίον (214-216).

[10] It is not by chance that this is how human beings lay their legs (they keep them slightly apart) when they want to assume the position of maximum balance while standing upright.

function. But exactly what was the κριοδόχη in this context? From the description of another ram-tortoise treated both by Athenaeus and by Vitruvius, i.e. the ram-tortoise of Diades, we learn that the word κριοδόχη means the compartment of the ram. However, in Diades ram-tortoise was installed a rested ram, thus making it easy to imagine the κριοδόχη as a sort of cavity placed on the ἐσχάριον, on the inside of which the ram would slide. Here we have to face a suspended ram instead, hanging from a height of a 30 cubits and swinging over the covering roof of the tortoise. Clearly then, the κριοδόχη cannot be composed (like in Diades' tortoise) of a supporting floor or of a closed compartment. Thus, we need to imagine it differently. The continuation of the text gives us other elements on the matter.

In the following sentence Athenaeus completes the description of the κριοδόχη[11]. It is interesting to notice that here Athenaeus mentions for the first time the ram. The fact that the ram appears exactly in relation to upright elements on the two central σκέλη, confirms what we said earlier: that the two central σκέλη were used to raise and hold a structure made of beams, winches and ropes, aimed at supporting the ram. But let us follow the passage.

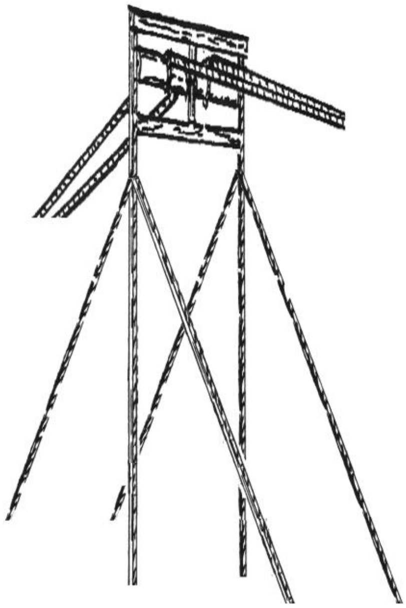

Fig. 1: the κριοδόχη.

At their upper tips were placed a περικέφαλον. It could not have been a simple beam but something wider, like a small platform (ἐφαρμόζω). This is the highest element of the engine. Lower, between the two σκέλη is then fastened a horizontal crossbar (διάπηγμα), parallel to the περικέφαλον, which creates a rectangular vertical space enclosed between the two horizontal crossbars and the upper part of the two σκέλη. The two horizontal crossbars are then fastened at their midpoint by an upright timber resulting in a splitting of the rectangular space longitudinally in two parts. Onto each of them is fixed a winch, from which hang the cables holding the ram. The ropes of the ram go therefore through this rectangular vertical space. It would be reasonable to imagine these winches a few cubits lower than the top of the central σκέλη (28 cubits). The ram however would have hung lower and precisely in the space between the second crossbar and the transverse beam of the tortoise's roof. However, besides the specific positions of each element, it is clear that this structure represents the κριοδόχη (the ram compartment) of the engine as it is aimed to receive, hold and move the ram. In order to complete the κριοδόχη we must also insert the other four σκέλη, whose function is now finally clear. When the ram was in action, the κριοδόχη must have suffered from strong swings. Just two σκέλη, for as solid as they could be, would never be enough on their own. It is therefore reasonable to believe that the purpose of the other four was to shore up the first two. Unlike the two central legs, there is no mention of them as being όρθιος, which might presuppose that they were placed in a markedly more slanting position. So here is the solution I would like to advance. Each 30-cubit σκέλος had at its front and at its back, a couple of 24-cubit σκέλη bowed exactly in the direction of the main σκέλος and converging onto it. In this way the whole structure holding the ram gained stability and balance.

[11] Εφαρμόζεται δέ έπαυτών περικέφαλον καί μέσος άλλο διά τών σκελών διάπηγμα. Καί άπά μέσον τού τε περικέφαλου καί τού διαπήγματος πήγνυται ξύλον ορθιον καί έφ΄έκατέρου μέρους τού παγέντος καί τών σκελών έμβάλλονται όνίσκοι τετορνευμένοι έξ ών τά öπλα έξήρτηται τά άνέχοντα τòν κριόν (217-221).

After that, a device called θωράκιον is introduced (221-223). Most likely it was a big metal parapet working as a shield for the men (no more than a couple) who stood on the περικέφαλον working as lookouts. Athenaeus says that the περικέφαλον was fixed to the κριοδόχη, which makes us understand that he didn't consider the περικέφαλον as an element belonging to the κριοδόχη dìqh. This sounds strange because it lies on the 30 cubit legs of the κριοδόχη, but in a certain way we could reasonably agree, because the περικέφαλον itself didn't play any role in holding the ram.

The ram

From now on the subject switches from the tortoise to the ram carried on it. First of all Athenaeus provides its **dimensions** (224-226). After that he describes its **iron tip** (226-229) and then he deals with the ύπόζωμα ύπόζωμα, an ingenious system of assembling several wooden juxtaposed beams (229). In a nautical context such systems were used to strengthen the keel of ships. Here however it is obviously used to create particularly long rams. Both in the case of the ram as well as in the case of ships, the binding element was made by ropes or wooden splints which were then placed longitudinally to the elements to connect and then fastened with ropes in order to keep them firmly joint together.

The ram was held in the middle by **chains**[12] (αλύσεις) wound three times around its trunk. These chains were described as being πηχυαίαι (of a cubit), but Schneider-Schwartz[13] preferred amending πηχυαίαι with παχείας, i.e. heavy. They probably assumed that the measure of one cubit does not match with the context, as it is too big if referring to the thickness and too small if referring to the length. On the contrary there is no problem in assuming that it refers to the length, as long as we imagine their position and their function slightly differently from the way it has been done previously. The chains did not stretch for the entire distance between the winches of the κριοδόχη and the ram (in that case Schneider-Schwartz would be right to consider it as being too small) but only along its last stretch. For the first part, this distance was covered by ropes coming from the winches of the κριοδόχη. These ropes —already discussed by Athenaeus in 220 (τα όπλα [...] τα ανέχοντα τόν κριόν) and soon again in 233 (όπλα αποτεταμένα [...] έκ τής κριοδόχης)— were then linked to these chains, which increased their extension for the measure of a cubit before being wound around the ram. There must have been more than one of such bindings. In fact Athenaeus goes on talking about the central one (230-232), which lets us imagine that there have also been some other ones. It was wound around the ram for a length of 5 palms and was surely the strongest. Although there are no ways to prove it, it's very likely that there were in all three bindings and consequently three suspending points, located one in the front, just venid the iron part, one in the middle and one in the back. Such a configuration is in fact ideal for controlling the movements of the ram.

After telling rapidly that the ram was covered with rawhide, Athenaeus goes back to the **ropes holding the ram**[14], which he had already mentioned in 220-221: τα όπλα [...] τα ανέχοντα τόν κριόν. But because he had just talked about another order of όπλα, i.e. those of the ύπόζωμα (229), he repeats some characteristics of other ones in order to prevent any confusion with his current subject. After that, he moves on talking about the connection between these ropes and the iron chains extending them. Here we learn that the rope of each of the three suspending points were not connected just with one chain but with four of them.

Obviously also these **chain-tracks were covered** with rawhide[15]. Then he explains the reason for this covering and here he says something really unusual, namely that the chains should be kept out of the sight of the enemies. In fact in all manuscript it is written: πρός τό μή όρασθαι, but this expression does not make any sense in this context, nor can a plausible solution be found by strictly sticking to the dictation of the codexes. Probably it is only the verb όρασθαι that is wrong. Giving a better look at the manuscripts, we notice that most of them have a blank space exactly before this verb. It's then not unlikely that the form όρασθαι is wrong and that originally another one was at its place. So όρασθαι must be changed with a longer verbal form, which, on one hand, could fill the blank space, and the meaning of which, on the other hand, could be more relevant to the context. A form which seems to satisfy both these requirements is συγκεκρασθαι. In this way the cover of rawhide around the chains would gain a plausible justification, as it would be used to avert the danger that they unduly intertwined.

Now the whole pass from the κριοδόχη to the ram is complete. The ram was held by three suspending points, in each of which it was bound by chains, from whose windings four chain-ends emerged. All this endings were connected just to one rope, which reached the κριοδόχη and hung from it. At this point one could rightly wonder where these hanging parts of these ropes would go. Athenaeus does not explain it. A reasonable answer could be that the ropes, after being fastened to the winches of the κριοδόχη, would descend vertically through the centre of the machine down until the έσχάριον, where a

---

[12] καί διαλαμβάνεται κατά μέσον έκ τριών διαλημμάτων άλύσεσι πηχυαίαις (230).

[13] *Op. cit.*, 26.

[14] Τά δέ öπλα άποτεταμένα έκ τών όνίσκων τών έκ τής κριοδόχης καί άνέχοντα τὸν κριόν έχει τάς άρχάς άλύσεσι σιδηράς τετραπλάς πεπλεγμένας (232-235).

[15] Καί περιβεβύρσονται αί άλύσεις πρὸς τὸ μή συγκεκράσθαι (235-236).

team of men (safe from any danger thanks to the planking of the roof) would control the movements of the ram by pulling and releasing them. If this is the case, as I believe it is, we need to suppose that the central storey with the missile battery (βελοστασία) mentioned before, was only placed in the anterior part of the engine, while in the central part, the volume between the έσχάριον and the covering boarding, was made of a single space, in which the ropes could freely go through.

ALENTEJO (PORTUGAL) AND THE SCIENTIFIC EXPERTISE IN FORTIFICATION IN THE MODERN PERIOD: THE CIRCULATION OF MASTERS AND IDEAS

Abstract

The question of mobility in architecture or engineering is an ancient process that grows with the rise of the professional group. History testifies several forms of this mobility (migration, emigration, mission, availability) and with a direct relationship to the importance of the professional status or the power of political and economic institutions (public, private, military and civilian, secular and religious). During the modern period, master architects, engineers and experts in a wide range of other fields travelled all over Europe disseminating their ideas, and in Portugal specialists of other nationalities had a significant influence. The advent of gunpowder and greater sophistication in construction techniques meant that the art of fortification came to be regarded as constituting military engineering. A large number of architects and engineers working in Portugal from the 16th century followed a geometrical pattern featuring angular bulwarks and regular shapes, and they were important figures in the training of Portuguese architects and engineers and in Portuguese military architecture, which ended up be exerting an influence abroad. Around a hundred engineers from abroad worked in Portugal following the Iberian Union, taking part in operations during the Restoration War (1641-1668) to reinforce the land border, specially in Alentejo, because the topography of the region made it vulnerable to attack by land, accounting for the high concentration of fortresses; coastal fortifications were only reinforced/constructed much later, although some plans were produced during this period. John IV, in 1640, set up the Council of War and the Border Commission, whose well-defined role was to inspect fortifications and deal with all questions in this area. The translation of treatises, the national book production in the field, the richness of maps and imagery produced, are also witness of the vitality and interest aroused by fortifications in Portugal.

During the modern period, fortresses and strongholds reflect synchronous scientific and technological advances, also denoting the deepening of specific knowledge that would derive into the appearance of schools and of an immense corpus of treatises of diverse, although confluent, subject matters. Indeed, the scientific character of these fortifications and the works of military engineering allow us to demonstrate and strengthen the relationship between science and technology from the

16th to the 19th centuries. Fortifications, during this period, expressed, beyond their military content, an ideological testimonial, offering an example of harmony between military techniques and the historical moments that frame them, and therefore could be interpreted as multidisciplinary documents: urban quality and landscape environment, architectural and urban value, typology and morphology.

The appearance of pyroballistics and its widespread usage in battlefields led to alterations in the fortified spaces, in order not only to improve the fortified structures themselves, so as to enable them to resist attacks, but also to respond to the need of installing artillery pieces and cannons for defence. Indeed, the bulwarked fortification, relying on angular bulwarks, was conceived not only to protect the surrounding terrain, but also the territory behind it. From the middle of this century (the 16th) we see a multiplication of fortification plans in several European cities, in which we can notice the existence of transitional plans by the presence of rounded bastions, adapted to artillery.

The circulation of masters and ideas, in the most diverse domains, characterizes the modern period in a European level. Architecture and engineering were determining fields in this panorama, and, in respect to Portugal, the presence of Italians, Flemish, French, and others, would end up influencing creation in these matters. Considering the classical division of architecture into civilian, religious and military, the latter was always considered minor by historiography and treatise writers, especially given the primary objective of a strict functionality. Still, the advent of pyroballistics and the greater technical demands in constructions in the modern period, in terms of military architecture, lead to the latter being increasingly considered as a science that should be grounded in practical knowledge, in the work field of military engineers. Already in 1557 Lanterini (*Due Dialoghi*) compared fortification to the medical science: not only was it a practical work, it was also a faculty, a science and an art form, because it called upon mathematical principles in search for forms and proportions. The Vitruvian conception, that considered fortifications as public buildings, also concurred to the slow acknowledgement of military architecture as an autonomous field within architecture; we should also bear in mind that, for Sebastiano Serlio engineers were *"architects of war"*, that designed other kinds of buildings during peace time.

Portugal, in the early modern period, witnessed several initiatives due to the confirmation of their borders; in this matter, we should highlight the work of Duarte d'Armas in 1509, by mandate of king D. Manuel, and who, during approximately 5 months, confirmed the defence points along the border with Spain, from Castro Marim to Caminha. This confirmation lead to the survey of 55 castles and fortresses, a work he would organize in two volumes, which hold 114 panoramic charts of 57 settlements and plans of 51 forts along the border. In its drawings and legends, the author reveals details about the constructions and their implantation, today considered essential for their understanding and analysis: apart from the military elements, such as strongholds of the castle and barbicans, *atalaias* [tower houses] and watchtowers, living quarters of the garrison and of the *alcaide* [governor of the fortress], access zones, arrow slits and cisterns, we can notice as well the presence of elements from the daily lives of local populations, (wooded areas and cultivated zones, water lines and bridges, mills, churches and convents).

Geometric organization of space with angular bulwarks and regular layouts had several foreign interpreters in Portugal from the 1500s on, who were instrumental both in the education of national masters and in Portuguese military architecture itself that manifested in facts surpassing the national geographic context. Indeed, this change in building techniques took shape all over the Portuguese space, in the continent as well as overseas (Moreira: 1988, 1989, 2001). These interpreters (approximately 100 French, Flemish, Italian, Dutch, Swedish and English engineers and architects), stayed in Portugal after the dominance of the *Philip kings*, and later participated to the reinforcement of the terrestrial border during the Restoration War (1640-1668).

Thus, in Portugal, during the 16th century, we find the office of «master of construction of walls and fortresses», belonging to many Italian masters: Tomaso Benedetto da Pesaro; Filippo Terzi; Giacomo Palearo (Captain Fratini); Giovanni Battista Cairati (in the fortification of Malaca, Ormuz, Mombaça); Tiburzio Spannocchi; Giovanni Vicenzo Casale; Leonardo Turriano[1]. The Philippine period, particularly under Philip III of Portugal, corresponds to a policy in which fortified spaces served the image of the reigning power: it is an architecture without ornaments, in which geometry and proportions so highly prized by the Iberian monarch and so widely practiced by the military engineers he financed, were prioritized. This policy would manifest in the construction of small fortified places above pre-existent burgs, dominating them, a policy that, in order to prevent the uprising of local populations, the Spanish monarch would end up not implementing in Portugal. Here, he chose to reinforce the coastline or to build new bulwarked perimeters surrounding old castles. Military engineers were particularly alerted to the need to include the symbology of royal power though visible elements in these fortifications, which were also meant to impress the enemy: the emblems over the doors, on the walls and on the bulwarks were designed for this purpose.

[1] Before the Philippine period, we had Ravenna, Tiburzio Spannocchi, being born in the dukedom of Urbino and in the Pontifical States, excluding the rival powers such as Venice, the Spanish viceroyalties and their political allies such as Genoa and Florence. Under Phillip II technicians came from regions faithful to Spain, such as Lombardy (the Cairati, the Fratini, Turriano), some Florentines (Casale, Filicaia) and from the Abruzzi (the Antonelli).

The political convulsions experienced in the European panorama lead to the importance given to military construction, that could only be afforded by the greatest monarchies or some great Houses (such as the dukedom of Urbino) due to the expenses they implied, but that, at the same time, served as a statement for those who could afford them. These expenses were due to their high level of technical expertise and to the specialization required for designing them, as well as to the materials used in these defensive systems, and also to the need to assure the education in the art of building fortifications, above all of military engineers. In the case of the Iberian Peninsula, foreign military engineers were well paid and acknowledged; they remained in contact with the Court and with powerful nobles, which enabled them to assure the livelihood of their close relatives who shared the same craft, leading to the appearance of whole generations of engineers such as the Fratini or the Antonelli. A similar phenomenon would later take place with the generations already educated in Portugal, as was the case of the Serrão Pimentel.

In the 17th century, the Restoration War between Portugal and Spain dictated a need to reinforce the terrestrial border. A new attitude towards the importance of a defensive reinforcement had taken seed with the ascension to the throne of king D. João IV, in December 1640. Parallel to the appearance of a permanent army and auxiliary bodies, the Council of War and the Border "Junta" [Assembly] were created, each with very well defined functions, meant to inspect and deal with all matters relating to fortifications. Both this Council and the Junta acted upon new geographical, administrative as well as military policy, due to the creation of six military provinces, each with its own governor, Alentejo being the largest, with more than twenty six thousand square kilometres.

As for this last region, we should highlight its topographic characteristics, that made it vulnerable, hence the strong concentration of military posts between Moura and Castelo de Vide (responding roughly to the location of the Spanish ones, opposing them from the other side of the border), and the priority given, also during this period, to the defensive reinforcement of inland cities such as Évora and Beja. To this concentration also corresponds a diverse typology, with distinct interventions, from the wholly bulwarked enclosure (Elvas), to the building of defensive points of lesser dimension (isolated bastions, forts) that varied as well according to the priority of enemy attacks. We underline the predominance of elements privileging dynamism and mobility, from which the artistic perspective should not be alienated. Their construction was the most impressive source of State expenses, exhausting, in 1641, 60% of its revenues, given that those interventions were synonymous to a high level of expectations regarding construction, and implied knowledge of new techniques and military tactics.

Within this context we find the character of Luís Serrão Pimentel, author of the *Methodo Lusitano* (published posthumously by his son, Francisco Pimentel). He was responsible, since 1647, for the Lecture on Fortification and Military Architecture for the education of Portuguese military engineers, at a time in which those working on fortifications were mainly foreign engineers (French, Italians and from the Low Countries), some of which had already been in the Peninsula serving the "Philip kings", and whose work reflected the abandonment of the Italian models for the Nordic ones (from the Dutch and German schools), with fortifications designed for the interior of the polygons, terraced profiles in taluses adapted to the different terrains, the return of angular watchtowers, an abundance of external works, elevating the scientific level of the fortification. Serrão Pimentel basically inspired himself, from a theoretical point of view, in Adam Freitag, Mathias Dogen, Goldman, Marolois, Coheorn and Stevin, while at the practical level he coexisted with some foreigners active in Portugal at the time. We should also stress the fact that the question of topographic survey cannot be separated from the works of military engineering and architecture: the design of fortifications either depended upon pre-existent work at this level or lead to the assessment itself, hence the relation between 16th century Portuguese cartography and military engineering. We also believe that several of the implemented projects, if valuable under a military perspective, do not prove as much under a strictly cartographic point of view (absence of details from the terrain).

At the same time, we find, in the Alentejo of the 1600s, among many others, João Pascácio Ciersman (Dutch), a Jesuit priest, known as Cosmander (in charge of observing all strongholds along the border, suggesting the reinforcement or the creation of fortifications according to the "Dutch method"), Nicolau de Langres (French engineer), Jean Gillot (Dutch), P. Santa Colomba, the author of treatises Manesson-Mallet, all under the orientation of chief-engineer Charles Lasart. During the long period of conflict between Portugal and Spain (1640-1668), many of these engineers worked for both kingdoms (Langres, P. Santa Colomba, Cosmander), while some Portuguese military engineers also started to develop work in this Province, as was the case of Mateus do Couto (nephew).

With Serrão Pimentel we see the achievement of the ambition to educate national masters in the area of military engineering, that would continue in the following century and that Azevedo Fortes's book *O Engenheiro Português [The Portuguese Engineer],* implements. This author acknowledges as indispensable to the education of a good engineer knowledge of the areas of Arithmetic, Elements of Euclid, Practical Geometry, Trigonometry, Fortification, Attack and Defence of strongholds, the usage of the Mathematical instruments pertaining to his profession, the method of designing plants and topographical charts with their profiles, elevations and façades and the means to draw; he also should not relinquish some knowledge in the area of artillery. All of these matters, to the exception of the last, are treated in the two volumes of the above-mentioned work.

We find some references to these matters, that we emphasize, in the Portuguese Treatise written in the 17th century. In Luís Mendes de Vasconcelos's *Arte Militar*, in 1612, we have allusion to Arithmetic, Geometry, Astronomy, Geography and to the practice of the Military Art[2].

This corpus of treatises reached its greatest splendour in the period after the Restoration, in the above-mentioned work of Luís Serrão Pimentel – *Methodo Lvsitanico de Desenhar as Fortificaçoens das Praças Regulares & Irregulares [Lusitanic Method of Drawing Fortifications of Regular and Irregular military posts].* In this work, the author, who had been the kingdom's chief-engineer since 1671, criticises some European theorizers, such as Blaise François, Count of Pagan, from the so-called second French school of fortification, before Vauban's advent. Pimentel inspired himself in the example from Holland, praising the ability to resist proven by their fortifications before the Spanish. Only after another half century do we see the appearance of an author of similar importance: the already mentioned Azevedo Fortes, also chief-engineer of the Portuguese kingdom since 1719, with his work *O Engenheiro Português [The Portuguese Engineer]*, published in 1728 and 1729. Although he praised Vauban, specially in his first method (initiated in Lille, in 1667), he claims to follow *"(…) hum novo methodo de fortificar as Praças tirado do mesmo Vauban, do Conde de Pagan, e do Cavalleiro de Ville, (…) e soube fazer escolha do que cada hum delles trás mais accomodado à melhor defença, ajuntando-lhe as suas proprias refleçoens militares (…)"* ["(…) A new method of fortifying military posts taken from the same Vauban, from the Count of Pagan and from the Chevalier de Ville (...) and knew how to chose whatever from each one of them was better adapted to the best defence, adding to these his own military reflections (…)"][3]. This method, defended by an anonymous writer, ventured on an aggregate of Vauban, Pagan and Antoine de Ville's ideas. Still, Azevedo Fortes does not shy from mentioning the influence of the Dutch fortifying method in Portugal during the period after the Restoration, stating that even engineers coming from France at the time followed the Dutch method.

During this time, several translations also circulated within Portugal, for instance, of the writings of Deville (1646), Fournier (1649), Antoine de Ville Tolozano (1708), and Mons. Pfeffinger (1713). At the same time, Manesson Mallet published in Paris, in 1671, *Les travaus des Mars*, in which we can find engravings representing fortifications in Portugal up to that period. These works are now part of the valuable collections of some libraries in Portugal, particularly the National Library [*Biblioteca Nacional*] in Lisbon and Évora's Public Library.

The practical application of these treatises as far as construction is concerned can be found in several fortresses in the Southern part of Portugal, particularly Elvas, the "key to the Kingdom"; in this case, worked Cosmander, in 1643[4], Pedro Girles Saint-Paul[5], Nicolau de Langres[6] and another French military engineer, Pierre de Santa-Colomba.

Notwithstanding, the foreign influence would continue in Portugal, as when the Marquis of Pombal solicited, in 1762, the services of Guilherme de Schaumbourg-Lippe[7], who intervened in the construction of the fort of Graça, in Elvas, according to the teachings of Sébastien Vauban; the project was implemented, with some additaments by coronel Guilherme Luiz António de Valleré, until 1792.

Apart from the many projects that came down to us, one of the most interesting iconographic evidence of military architecture and engineering from the modern period in Southern Portugal is offered by the superb glazed tile panels from the Espírito Santo convent, the main building of Évora's University.

The ensemble of glazed tiles, called *"azulejos"*, dating from the last years of the 1730s and early 1740s, was artistically inspired by Dutch models, even though its manufacture was Portuguese. Their application to the building walls resulted from a building campaign under the reign of D. Joao V, and happened at the same time as the application of marble elements and exotic woods. The subject matter of the tiles adorning the rooms around the main cloister of the Colégio do Espírito Santo is very broad; each room develops a specific theme. These range from themes inspired by Classical Antiquity to those conspicuously religious; particular attention is given to the scientific context and to the technological advances from that period; we should highlight the room devoted to Astronomy and Geometry. Not only do we see instruments represented – a quadrant, compasses with straight and curved points, squares, levels – but we can observe their usage and practical demonstration. The importance of calculation and its relation to architecture and military engineering continue in the following panels, in which scenes from an attack to a bulwarked military post are represented; we can notice the positioning of the

[5] In Elvas since 1641, and whose presence in the military post of Almeida would also be noticed.

[6] Who also worked in the fortifications of Évora, Elvas, Estremoz, Campo Maior, Castelo de Vide, Juromenha and Moura.

[7] Know in Portugal as the "count of Lippe", he was Field Marshal of the Portuguese army and commander of the Anglo-Portuguese forces during the last year of the Seven Years War (1756-1763). His actions manifested essentially regarding discipline and the instruction of the troops, hence the publication of the text as *Regulamentos de Infantaria e de Cavalaria [Infantry and Cavalry Regulations].*

army, the observation of the stronghold in order to establish a strategy for attacking it, the trajectory of the attacking projectiles, as well as the defensive response of the stronghold under siege. The coat of arms of the Portuguese Royal House is also present, reminding us of the ubiquity of the monarchy in the great building projects designed for the kingdom. In this case, the implicit presence of D. João V, not only through the royal commission for the tile panels but also in its up-to-date characteristics, reflecting upon the whole kingdom the fact that the king knew the very best of what was happening in Europe concerning science and technique, and their application on bulwarked fortified structures.

On the other hand, all through the remaining rooms we can observe the presence of several military elements – garrisons, forts, gates – and their relation to the surrounding landscape; the armies of the time, their deployment and positioning in the terrain, what weapons they used, are also constant.

In another location within the same building, we find tile panels devoted to the four elements – Air, Earth, Water and Fire – in which we can observe, precisely in the panel devoted to Fire, allusions to the casting of cannons, to pyrotechnics, and to fireworks, as well as the only representation in all the tile panels in the building of individual firearms.

From the entire ensemble, we retain two references that we find essential to consider about the theme we proposed to develop: the circulation of masters and ideas in Portugal in the area of bulwarked fortifications:

- On one hand, the tile panels demonstrate as for their conception a clear predominance of the Dutch school: regarding the landscape elements, the relief, the constant presence of water, always relating to elements of military architecture. Given the date of the panels, some fortifications incorporated into the landscape or near the water lines end up presenting characteristics pertaining to the so-called "transition fortification", retaining semi-circular and cylindrical elements next to angular forms, normally pentagonal, but still without the bulwark, a characteristic element of modern fortification.
- On the other hand, and if indeed the drawing of the panels was inspired by Dutch models, the fact that they were made in Portugal is also synonymous of their acceptance, as the typology of the fortresses represented seems to be a common element of the Portuguese landscape of the time. This acceptance regarding foreign influences continues, in these tile panels, in the representation, already in their latter phase (this one, possibly not only made but designed exclusively by Portuguese) of the Japanese world, their people, their ways and their heritage.

Conclusions

1. Bulwarked fortifications or fortresses "in the modern way" imposed themselves in Europe through different schools and for a long period of time, leading to a whole set of adaptations and options in relation to their original programs, in order to improve them;
2. Portugal, and in particular the Alentejo region, have been the stage, from the 16th to the 18th centuries, for the presence of technicians from the fields of military architecture and engineering, originating from different European countries; these technicians, by the monarch's request, worked and participated in the reinforcement of Portugal terrestrial and coastal borders as well as in some inland settlements, considered to be strategically significant;
3. The analysis of the creation and evolution of the fortified systems, besides giving undeniable evidence of the political situation at the time, the territorial dimensions of the country and its overseas dominions, the technical and military advances, also allows to consider the importance of the legacy that remained;
4. Of this vast heritage, not only should the buildings themselves be acknowledged and preserved but also their remaining images and representations; if ancient cartography and the royal commissions are a particularly important field of study, the evidence provided by glazed tile panels also appears to us as essential for the understanding of foreign influences in Portugal, particularly in the Alentejo.

Abstract

This paper focuses on the rise and partial fall of the Catalan civil engineers and their heterogeneous technological ideals during the II Spanish Republic (1931-1939). The international exhibition of Barcelona, the international economical crisis and the birth of an autonomous government in Catalonia prompted civil engineers to actively participate in economics and politics.

The study of the Catalan engineering ideals and projects will take account of the local analysis on Technocracy which have recently appeared (e.g., France, Greece, USA), in order to complete the international panorama and to understand the continuous articulation between the national and international issues as "sides of the same coin". Like machines or technical skills, local engineering thought cannot be explained by linear diffusion or "spontaneous generation"; then, it will be necessary to explore specific (socioeconomic, cultural, psychological) contexts.

[1] This paper is a transcription of my communication at the 4th International Conference of the European Society for the History of Science (Symposium "Knowledge and technology in the Mediterranean basin", coord. Àngel Calvo, 20/11/2010). However, some minor changes and bibliography have been included. It is a summary of a chapter of my PhD Thesis, *"Tecnocràcia i Nacionalisme tècnic a Catalunya als anys 1930. Els enginyers industrials, de la matematització de la màquina a la racionalització de l'Estat"* ("Technocracy and Technological Nationalism in Catalonia during the 1930s. The industrial engineers, from the mathematization of the machine to the rationalization of the State"), supervised by Antoni Roca Rosell (UPC) and supported by the Catalan Government (AGAUR, FI-B grant). Besides, this work is part of the research project *"Ingeniería, matemáticas y sociedad en Cataluña y España, siglos XVII-XX"* (Spanish Ministry of Science and Innovation, HAR2010-17461, HIST).

[2] In this paper, I use the capital letter "T" or the lower case letter "t" in aims to distinguish Technocracy, the Technocrat Movement targeted in 1933, from technocracy, a long-term ideology.

"Why should I bother trying to save energy anyway?
We simply have to use less energy, more efficiently.
Most energy experts agree…".

(e·On Advertisement, Green Park Tube Station, London, 11/11/2010)

"There are a large number of different bookkeeping devices whereby the distribution to, and records of rate of consumption of the entire population can be kept. Under a technological administration of abundance, there is only one efficient method—that employing a system of *Energy Certificates*".

(*Technocracy Study Course*, 1934)

Introduction

In August of 1933, industrial engineers in Catalonia publicly expressed their opinion about a powerful word. This word had been shocking the world -and, particularly, Catalonia- for several months. This word directly brought their profession into the focus of public attention but it seemed to disturb them. It was a kaleidoscopic word which circulated so quickly as the Lockheed Vega airplane. The word was: "Technocracy".

In August of 1933, *Tècnica*, the Journal of the Association of Industrial Engineers of Barcelona, dedicated its editorial to the affair. This would turn out to be the first and the last time "Technocracy" appeared in its pages. It seemed to be a metaphor for an ephemeral international debate that rose and fell in 1933. Nevertheless, the ephemeron contained a former reason which would permanently shape governments and societies: more "-cracy" to "Techno-", more government to technicians.

A word in transit

In 1933, at the worst point of the 1929 crisis, a word full of "mystery" (according to contemporaries), produced a "strange furore [sic]", "raising hopes, fears and doubts" [Arkright, 1933; Allen, 1933]. The furor started some months before, when the director of the Energy Survey of North America, Howard Scott, let slip about a smash ideology beyond Capitalism, Socialism, Communism or Fascism in an interview reproduced in the *New York Times* and the *New York Herald Tribune*. Scott claimed: "(America) finds herself in the dilemma of having to desert one system which has become obsolete and simultaneously to design a system to take its place" [quoted in: Allen, 1933].

"Technocracy" appeared like mushrooms in magazine articles and newspapers columns [Adair, 1970]. The Continental Committee on Technocracy, the group of technologists led by Scott, defined its methods as the "result of a synthetic integration of the physical sciences that pertain to the determination of all functional sequences of social phenomena" [Scott, 1933]. And, they proclaimed to have found a scientific technique of making decision when "no political method of arriving at social decisions (was) adequate" [Scott, 1933].

A huge debate was animated by enthusiasts, reformers and critics of the radical theory, by the Right and the Left, by women and men, by specialized experts and generalist speakers. Obviously, in these attempts to popularize it, the word was changing in meaning to serve the visions of the popularizers.

Nevertheless, the continuously reformulation of the ideas was integrated in a former process. The word was coined in 1919 by the Californian engineer William Henry Smyth, and Howard Scott and Co appropriated it. At the same time, the redefinition took into account other early economic criticisms, e.g., Veblen's or Frederic Soddy's. Moreover, the scientific framework came from long ago, especially from late nineteenth century thermodynamics [Rabinbach, 1990]. Thus, there was no real novelty in Technocracy: neither in the container nor in the content. But, the globalized economic struggle and the social hopelessness gave a good opportunity for this astonishing lexicon to gain political ground.

In North-America, Technocratic associations and committees grew up and joined up marginally employed people (with high number of women involved). Supporters even imagined a utopian "life in a Technocracy" where, for example, adultery or jealousy had no place [Loeb, 1933]. However, the movement never rose broadly. The main US engineering associations did not support them, nor did entrepreneurs and politicians, nor the Left wing [Akin, 1977].

"Technocracy" soon arrived on the other side of the Atlantic. England seems to be the first reception *nest* of these ideas from the New World. But the European focal point was Geneva, during the International Conference on unemployment. Spanish newspapers picked up on the discussions in Geneva. One week after, the most recognized Catalan engineer at this moment, the military engineer Marià Rubió i Tudurí, was one of the first voices to open the discussion in Catalonia. He wrote in the conservative newspaper *La Vanguardia* (22/01/1933): "Technocrats seem inclined to become a sect". More benign was Pedro Gual Villalbí, the secretary of the employers' association in Catalonia, Foment del Treball, and member of the Francoist National Economic Council just after the Civil War (1936-1939): "It is not a tendency to neglect; who knows if it contains the germ of principles for the future organization of society" (*La Vanguardia*, 06/05/1933). But he was the only public person who wanted to be identified with the Technocratic theories. Fierce contrary opinions were reflected in magazines and newspapers related to very different ideological tendencies, such as catholic Catalanism (*L'Esplai*), humanist Catalanism (*La Revista*, *Mirador*), Spanish Ultraconservatism (*Acción Española*) or Anarchism (*La Revista Blanca*). Everybody took Technocracy to be an attack to their particular projects of nation.

All over Europe, several books about Technocracy were published in 1933 –and not beyond this year. And Spain was not an exception. The *Revista de Occidente*, edited by Ortega y Gasset, translated Raymond Allen's *What is Technocracy?* And Allen's book became the best-known text about the old-new word in Spain. Nevertheless, there were also other attempts to popularise, discuss and critique the term. The only Spanish book specifically focussed on Technocracy was written by Eduardo Llorens, a scholar of the University of Murcia. He pointed out "the wrong starting point and the dismal failure of the methodology of the Technocrats" [Llorens, 1933]. Despite there was no evidence of real or potential support for Technocracy in Spain, more than one hundred pages were dedicated to this "failure". In addition to French, German and English texts, Spanish readers could also refer to a Columbian work, by Jorge Álvarez Lleras, who tried to link Technocracy with the theories of economist Julio Garavito Armero. But what public impact were specialist books having? Álvarez Lleras himself highlighted the limited reach of his own work [Álvarez, 1933].

One of the groups that could have participated in the social discussion with expert language (academic sphere) as well as with lay language (public sphere) was the Catalan industrial engineers. They had become the most reputed and organized professionals of technicians in the beginning of the 1930s [Lusa, 2006]. They represented the "applied scientists" that were placed in the midst of the debate [Nolan, 1997]. Moreover, they aimed to become the new "third class", between workers and employers, beyond politicians. Obviously, they had to know about Technocracy. But, publicly, they remained silent for several months. Actually, the library of the Association of Industrial Engineers doesn't preserve any copy of publications on Technocracy, nor internal documents, nor discussions in the assemblies of the Association, nor other evidences. But, the multidirectional transit of knowledge and ideologies –despite being hidden to recent historians– were clearly tangible to individuals at this time. The circulation of Technocratic ideas and ideals had mainly been supported by people who did not support them and the best way to block this centrifugal circuit was to neglect them.

Technocracy in *Tècnica*

Finally, in August, *Tècnica* broke the silence. Its editorial did not refer to the initial focus point in the US nor specific opinions, but to an ambiguous generalist idea around it. In response to the "comments" on Technocracy, the industrial engineers claimed: "Politics is AN ART [sic], and, then, it has no discipline but the weighted sense. On the other hand, it is forbidden to speak about politics in these pages". But it immediately continued with these words: "There is a lack of responsibility of government when it forgets corporatist technicians".

From the beginning of the editorial section, the introductory pages contained plenty of politics about "The industrial engineers in front of the Autonomous Statute of Catalonia" (September 1932) or "The engineers and politics" (January 1933) where engineers celebrated their access of engineers to high-ranking offices in the Catalan Parliament. Then, they did not mind speaking about engineering and politics: they rejected the use of Technocracy, likewise they had rejected to talk of other radical visions of technicians' empowerment, e.g., Le Corbusier's, Jacques Duboin' or Salvador Dalí's [Corbusier, 1933; Duboin, 1932, 1935; Dalí, 1928]. And the final cause is not related to the disagreement with some internal meanings of the word, but to the agreement with others. A lot of common language was shared by the faithful to Technocracy and the technocrats against Technocracy, such as governmental efficiency, abundance of material goods or improved distribution.

Engineers wanted to maintain their image of neutrality, objectivity and scientificity beyond the future changes of governments and the political ideologies in conflict. Curiously, the same image which had feverishly strengthened the new word (Technocracy) was being challenged by the word itself. The more engineers denied participating in politics, the more they could participate in politics.

Catalan industrial engineers were not the "baffled, unemployed mass of technicians who (had) been deprived of their functions by the decay of capitalism", as north-American Marxists characterized their compatriots [Foster, 1933]. Catalan industrial engineers had reached a public acknowledgment as well as an urban spatial position. They were part of the elite during the thirties, as I argued in some unpublished papers [Valentines, 2009, 2010]. In these years, the Association of Industrial Engineers was consolidated and had a well-defined project. Moreover, during the first years of the II Spanish Republic (1931-1939), the establishment of new autonomy for the Catalan territory permitted redefinitions in power correlations. One after another, the requests of industrial engineers were accomplished; the legislation of these years gives us evidence of the engineers' project of modernization, concerning technical offices, territorial planning, hydroelectric survey…: a project closely linked to the construction of the Catalan nation from long ago [Roca, 1988].

Last but not least, the Association alleged that the current political system –actually, any political system, except Technocracy– integrated within the Catalonian Statute could be acceptable as long as they had a firm position in the organization of the State: engineers were servants of the II Republic as long as the II Republic was servant of them. The editorial of July 1933, just the one before the editorial about Technocracy, was clear: "A lot of roads lead to Rome, and it can be added that we can go by different vehicles; by means of very different political systems (from English democracy to German Hitlerism), we can see how economic struggles are solved in every nation".

Nevertheless, the political neutrality of the Association was an illusion, a construction to unify very different professionals. It contrasts with the very different political and economic visions of them. In fact, some of the members of the Association had a very active role in the economic debates in Catalonia. In Spain, economics was a discipline in process of consolidation within the academic system. Historically, despite other specific institutions, the School of Industrial Engineering –the centre related to the Association– had provided the knowledge and skills to be an economist [Artal, 1976]. Then, the engineer and the economist usually were the same person.

Some engineers exalted Capitalism, such as Josep M. Tallada, who wrote a very well-documented book against the Soviet State [Tallada, 1935]; some others embraced Socialism, such as Estanislau Ruiz Ponsetí, who had participated in the Technicians Union of Catalonia from the twenties and who became one of the leading lights of the New Economy during the Civil War [Ruiz, 1937]; others were attracted by Italian fascism or by the reactionary modernism of the Roosevelt government. But, all reclaimed organization for the State and high-qualified experts for the organization. In fact, far beyond the theoretical corpus by Howard Scott, technocracy is a "transversal ideology", as Frank Fischer notes [Fischer, 1990]. In fact, such as productivism –the other parent of the 20th century modernity–, technocracy is "political promiscuous" [Rabinbach, 1990; Nolan, 1997].

Actually, some months after the rejection of the Technocrat movement, the Association started to prepare a set of economic lectures to debate the best structure to organize the state. Finally, in 1936, these were materialized. Technocracy, of course, was absent. For the first time, the Association conferences were broadcasted by Barcelona radio with the aim of improving "the education of our nation", it was written in *Tècnica* (April 1936). Nevertheless, the filo-fascist Antoni Robert claimed in his conference: "It is up to us, Engineers [sic], we are called to write the economic standing of our nation. We hope that our action will rise to the occasion" (*Tècnica*, May 1936).

As it was proclaimed in 1941, despite the defeat of Technocracy alternative debate, Technocracy triumphed [Akin, 1977]. The related consequences of 1929 and World War II gave the opportunity for the technicians to implement technocratic projects in very different political systems. The Greek "Technical State" (1931-1936) and the Vichy Republic seem to be the most radical, as Yiannis Antoniou and Antoine Picon have pointed out [Antoniou, 2007; Picon, 2007]. Nevertheless, the cases of the USA and Great Britain were more consolidated, as they have been studied by William Akin, David Edgerton, Michael Weatherburn [Edgerton, 2006]. The Spanish Civil War and the revolutionary context on the Republican side let some engineers, architects and technicians to think that a new era was starting: "the moment to implement the research results made by modern technicians to organize the new society" ["És el…", 1937].

Epilogue

The circulation of science and technology not only involves texts or practices, written or tacit knowledge, instruments or machines, but also the deep social ideologies inserted into them. Nevertheless, this core piece of science and technology usually has been overlooked by recent historians of scientific popularization, except in some case studies [Pohl-Valero, 2008]. These ideals are carried out on a broad "road network", with very different avenues, directions, traffic signals, vehicles and drivers. Transport –any transport– is regulated according to these factors as well as the merchandize being carried.

It can be noted that non-appropriation of arguments and technology can alter the traffic as much as appropriation. Appropriation and non-appropriation are always in tension, just like the public and non-public relationship.

Technocracy movement was very ephemeral, inconsistent: a bluff, at least in Europe. However, it permits historians to dialogue with the ideologies "in transit" about technology during the thirties and the actors involved in them [Secord, 2004].

FRANCESCO MAUROLICO AND THE RESTORATION OF EUCLID IN THE RENAISSANCE

Veronica GAVAGNA
Department of Mathematics, Università degli Studi di Salerno, ITALY
vgavagna@unisa.it

Abstract

The first printed edition of the Elements*, based on the medieval recensio of Campanus of Novara, appeared in Venice in 1482; some years later, in 1505, Bartolomeo Zamberti published a new (and quite different) translation based on a Greek code. The contemporaneous availability of two Latin editions –we could say two* editiones principes– *of the* Elements*, both unsatisfactory for different reasons, gave rise to different reactions among the European mathematicians: some of them embraced the cause of Campanus, some others the cause of Zamberti, and others rejected both Campanus' and Zamberti's redactions. In the last case, the absence of an established, shared and trustworthy Euclidean text, let some mathematicians write 'their'* Elements*. In this paper I describe the main features of the transmission of the* Elements *in the early Renaissance Europe and I focus my attention on the figure of the mathematician Francesco Maurolico (1494-1575). Maurolico (*http://www.dm.unipi.it/pages/maurolic/intro.htm*) was very unsatisfied with the available editions of Campanus and Zamberti and in a letter dated 1532 he announced an original publication programme about Euclid's* Elements*, founded on the following essential points:* 'emaculare'*, or to correct the available editions by mathematical mistakes,* 'reddere faciliorem'*, or to make easier, if possible, the Euclidean proofs;* 'coaptare' *or to choose every time the best logical architecture, the best proof, the best language between the two editions. In other words, he composed a new text coming from the joining of the two Renaissance traditions with many additions of his own. The* Elements "ex traditione Francisci Maurolyci" *–which are going to appear in the volume* 'Elementa geometriae' *of the* Edizione Nazionale dell'opera matematica di Francesco Maurolico– *were only partially published in 16th century, nevertheless it's possible to detect some influence in Clavio's fundamental recensio of the* Elements *(1574) and in Borelli's* Euclides restitutus *(1658).*

The first Euclidean project

In 1528, the Sicilian mathematician Francesco Maurolico (1494-1575) lectured on Spherics and Euclid's *Elements* on behalf of the Senate of Messina, his hometown. As he explained in a subsequent dedicatory letter to his patron, dated 1532, the unsatisfactory level of the available editions of the *Elements* convinced himself to prepare a new edition of the Euclidean text.

In the first decades of the Sixteenth century the editions of the *Elements* available to the scholars and known by Maurolico were essentially two: the *editio princeps*, printed in Venice in 1482 by Erhard Ratdolt and based on the medieval version of Campanus from Novara, and the Venetian edition of 1505, based instead on the translation of a greek code, made by the humanist Bartolomeo Zamberti. Maurolico surely knew also the version edited by Jacques Lefevre d'Etaples (Jacobus Faber Stapulensis), printed in Paris in 1516 and followed by numerous reprints and editions. In several documents, unfolded over an extended period of time, Maurolico expressed quite severe criticisms against Campanus and Zamberti. Actually, the medieval *recensio* showed additions, changing of definitions or differences in numbering sometimes questionable, while the translation by Zamberti mercilessly highlighted the very poor geometrical talent of the Venetian humanist. Finally Stapulensis, instead of critically merging the two traditions, simply juxtaposed the two texts, in the vain attempt to balance their shortcomings.

Faced with this situation, Maurolico set out to produce an edition of the *Elements* which was able to collect the best of the known traditions, possibly supplemented by his original contributions, in order to simplify and shorten the Euclidean proofs.

The guidelines of this first Euclidean project, which appears to be regardless of any literary integrity of the text or any philological respect, reveal instead a clear orientation to its mathematical restoration, a tendency which is after all shared by all the editions of the Classics that Maurolico was able to complete; it is not a chance that the titles of these works are always followed by the quote *«ex traditione Maurolyci»*, which connotes the works of Maurolico rather than that of any author treated[1]. As P. L. Rose has written, «to Maurolico's mind … there was nothing wrong with correcting classical treatises, as long as it be done by an expert mathematician. Nonetheless, Maurolico was certainly the most radical of Renaissance mathematicians in this respect».[2]

Announced in 1532 and developed, at least partly, in the following decade, the programme of restoration of the *Elements* would remain unfinished, but in the second half of the Sixties it picked up again, taking the form of an abridged edition of the *Elements*.

In this contribution we provide a brief description of the extant texts (§2) and, after analysing their most relevant mathematical features (§3), we try to trace the evolution of the Euclidean project by the Sicilian mathematician (§4), highlighting the problems that are still open (§5).

The extant Euclidean texts

The collection of Maurolican writings related to the *Elements* includes documents of various kinds: printed editions, holograph drafts, re-readings, compendia and numerous related fragments. A chronological ordering of the survived material leads, in the first instance, to classify the writings into two major groups: the texts written during the years 1532-1541 and the compendia of the years 1563-1567.

The various autographic writings dating back to the decade 1532-1541 witness a real dedication spent by the author in the construction of a new edition of the *Elements*. In fact, we have the following texts:

- a draft containing the first ten propositions from Book II, retained in the Ms. San Pantaleo 115 of the *Biblioteca Nazionale* of Rome, ff. 21*r*-22*v*, dated January 21, 1532;
- the drafts of Book V (November 5, 1534) and Books VII, VIII, IX (November 9, 14 and 19, 1534, respectively), corresponding to the folia 1*r*-39*v* of Ms. San Pantaleo 116;
- the draft of Book X (August, 1541), retained in the same code (ff. 40*r*-107*v*).

At present, we do not have any news concerning the missing drafts of Books I-IV, VI, XI-XII.

The extant texts are written with care and show just a few erasures. Maurolico's attention is focused on the proofs, since definitions and postulates are completely absent. Propositions, although numbered in the margin, are lacking in the statements. In this group of writings, the edition of Books XIII-XV of the *Elements* must also be considered, drawn at least in its essentials in 1532 and published posthumously (1575) in the miscellaneous volume titled *Opuscula Mathematica*; it is the only printed document provided by Maurolico about his plan of restoration of Euclid.

The second group of Euclidean writings consists of the following texts:

---

[1] Concerning Maurolico and the restoration (*restitutio*) of the Classics, see the papers by P.D. NAPOLITANI, Maurolico e Commandino, in *Il Meridione e le scienze*, edited by P.NASTASI, Palermo 1988, 281-316; Le edizioni dei Classici: Commandino e Maurolico, in *Torquato Tasso e l'Università*, edited by W. MORETTI e L. PEPE, Olschki, Florence 1997, 119-141.

[2] P.L.ROSE, *The Italian Renaissance of Mathematics*, Genève, Droz, 1975, 166.

- the compendia of Books XI and XII of the *Elements*, dated December 3, 1563 (ff.34*v*-39*v* of Ms. San Pantaleo 115)
- the compendia of Books I-X, written from January 28 to March 11, 1567 (ff. 2*r*-43*r* of Ms. Lat. 7463 of *Bibliothèque Nationale de France* in Paris).

The previous drafts appear fairly accurate on the whole, presenting few corrections and some additions in the margin. The only exception is the draft of Book X, characterized by successive additions and re-workings.

Maurolico interpreter of Euclid

1. The re-readings of the Thirties-Forties

The aforementioned dedicatory letter of 1532, which accompanies the printed edition of Books XIII-XV of the *Elements* (1575), ends with the promise of a global edition of the Euclidean work inspired by specific criteria: *emaculare*, that is to clean and correct the numerous errors of the printed editions, *reddere faciliorem*, that is to simplify and shorten, where possible, the Euclidean proofs; *coaptare*, i.e., each time choosing, among the known editions, the most streamlined logical architecture, the most convincing proof, the most suitable terminology. It is not excluded, in particular cases, that the existing proofs would be replaced by new Maurolican proofs.

The drafts of Books V and VII-X of the *Elements* dating from 1534 to1541, perfectly fit into this program, because they are a critical re-fusion of the Greek tradition with the Arab-Latin one, supplemented as necessary by the original contributions of Maurolico, who added, shortened and in case omitted proofs. To better understand what is meant by this statement, we see a little closer the Maurolican reworking of the theory of proportions, i.e. Book V of the *Elements*, starting from a brief description of the versions provided by Campanus and Zamberti.

Book V *ex traditione Campani* differs substantially from the translation by Zamberti in the following points: a different (and controversial) definition of proportionality[3], the inversion of two propositions (the 12th and 13th) and the addition –in the medieval recensio– of nine final propositions on the properties of inequalities between ratios. Maurolico does not slavishly follow one or another tradition, but tries to recast them critically. His draft, although free of definitions, clearly shows to adopt the definition of proportionality of the Greek text. The Sicilian mathematician also respects the 'greek' sequence of propositions, but does not hesitate to join eight of the nine Campani additiones concerning the inequalities between ratios. As regards the lexicon, as a rule Maurolico shows a preference for the one of the Venetian humanist Zamberti, but also partly follows the terminology of Campanus, for example to indicate some manipulations on the proportions.

Finally, when the proofs of the same proposition differ from each other, Maurolico tends to favour the version proposed by Campanus rather than the one by Zamberti, although in few cases opts for a personal solution.

The problem of restoring Greek mathematics, to Maurolico's mind, becomes the problem of establishing a comprehensive and mathematically reliable text. The Sicilian mathematician does not arise philological scruples, being convinced of the impossibility to really restore the true Euclidean text, so full of mistakes "of scribes and translators that Euclid himself, returned to life, could nor purge their works".

2. The **Elementorum compendia***: a reworking of the* **Elements** *in arithmetical key*

The impression we can get even from a superficial reading of the Euclidean compendia of the Sixties, is that of a clear distinction between the first four books and the next ones. In fact, while the compendia of the books dedicated to plane geometry (I-IV) are not significantly different from the tradition of the *Elements*, the remaining ones are reinterpreted according to a strongly arithmetical perspective.

The previous rigid dichotomy does not regard the compendium of Book II, which has always been interpreted by Maurolico according to this peculiar point of view. Actually, all the Maurolican survived drafts of Book II, including that of 1532, provide arithmetical alternatives to the traditional geometrical proofs of the first ten propositions. However these proofs are not completely original, because they are based, as stated by Maurolico himself in a scholium of Book IX, on the topics of the Campani adnotationes to proposition IX.16, which interpret in a numerical key the first ten propositions of Book II.

On the contrary, starting from the epitome of Book V, i.e. from the theory of proportions between magnitudes, Maurolico distinguishes himself by a highly personal approach, in which the definition of proportionality is the kernel of the theory, favouring the comparison of ratios rather than equimultiples.

---

[3] For a framework of the discussion on the theory of proportion in the early sixteenth century, see E.GIUSTI, *Euclides reformatus. La teoria delle proporzioni nella scuola galileiana*, Turin 1993.

The Sicilian mathematician constructs a general theory of proportions between magnitudes trying to bring the irrational ratios to rational ones, proving that the former can always be 'contained' in an interval bounded by the latter. In this way, the author tries – even if with some weaknesses– to ensure the generality of the theory by actually studying only the properties of rational ratios. It becomes immediately evident that the propositions in Book VII of the *Elements*, dedicated to proportions between numbers (VII.4-19), appear completely redundant to Maurolico, which summarizes them in one proposition only: "It has been proved in Book V everything regards ratios and proportions in general; this also holds for numbers".

Maurolico, however, does not restrict himself to eliminate this group of propositions from the arithmetical books, but he completely re-arranges their logical architecture. It should be noted, indeed, that the arithmetical books especially apply to be rearranged, because they are nearly free from a hierarchical logical-deductive structure, being rather grouped –especially Book VII– in main themes. Let us briefly see how Maurolico alters the structure and contents of the arithmetical books.

The central problems solved in Book VII, according to the Euclidean tradition, are the determination of the greatest common divisor and least common multiple of two and then three integers (VII.1-3, VII.34-36), and moreover the characterization of representatives of a given ratio and reduction to minimum terms (VII.20-22, VII.33). Instead, in the compendium of Book VII, Maurolico maintains the propositions regarding the determination of greatest common divisor and anticipates –from Books VIII and IX, respectively– some properties of plane and solid numbers, and of a geometrical progression. In this context, he inserts the following proposition that relates the algebraic powers to terms in continuous proportion: "The unit, the unknown, its square, its cube and its square-square are in continuous proportion" *(«Unitas, radix, quadratus, cubus et secundus quadratus, sunt continue proportionales»*, VII.8). This is a reminder of some interest, since Maurolico also left us a brief treatise on algebra[4] actually closely linked to this result, which allows him to present an equation as the equality of side powers of the unknown[5] and reduce the traditional six *«regulae algebrae»* to just four.

In the compendium of Book VIII, Maurolico inserts the propositions excluded from Book VII (that is the propositions mainly related to prime numbers) and the first 27 propositions of Book VIII, concerning the determination and the study of continuous proportions, the characterization of square and cubic numbers, plane and solid numbers.

The compendium of Book IX opens with six propositions devoted to the square and cubic numbers, and after propositions 7-21, which are not confirmed in the Euclidean *Elements*, the epitome concludes with the famous result on perfect numbers: «If as many numbers as we please beginning from a unit continuously be set out in double proportion, until the sum of all becomes first, and if the sum into the last multiplied make some number the product will be perfect» (proposition IX.23 *«ex traditione Maurolyci»*, i.e. proposition IX.36 of the *Elements*). Some applications regarding continuous proportions and most of the results related to prime numbers are then removed from the compendium, as well as the treatment of even, odd, even-times even and even-times odd numbers. Therefore, as it is evident, Maurolico deeply modifies the Euclidean arithmetical books, both in content, in methodological approach and logical architecture.

Maurolico and the educational project of the Jesuits

In the late Forties, the Jesuit Jerónimo Doménech, with the help of Ignatius of Loyola and the Viceroy of Sicily Juan de Vega, founded in Messina the Collegium primum ac prototypum with the purpose of creating a model of Jesuit University opened to external students. According to the intent of Doménech, the Collegium had to be the University of Messina, but managed by the Society of Jesus, which had to plan the courses and organize the lectures.

For about five years, i.e. from 1548 to 1553, the Collegium of Messina essentially supplied elementary and secondary teaching. Due to a series of clashes that arose between the Jesuits and the Senate of Messina, the project was not able to definitively take off and the educational activity of the Collegium was considerably reduced but, from 1564, a renewed understanding led to the activation of the Studia superiora, within the framework of the genuine *Ratio studiorum*[6]. The need to realize a new educational system related to the advanced courses, and the intention of involving the local scholars in the educational project, led the Jesuits of Messina to strengthen the relations with Francesco Maurolico.

The terms of the cooperation offered by the old mathematician to the Jesuits, were gradually extended from occasional advices to the development of an ambitious editorial plan for arranging all the sciences in an encyclopedia

[4] The electronic edition of *Algebra* is available on the website of the *Progetto Maurolico* (www.maurolico.unipi.it)

[5] Given the scale of algebraic powers, Maurolico considers 'side powers' of an assigned one, the equidistant powers from it.

[6] On the vicissitudes of the *Collegium primum ac prototypum* of Messina and the role of the Mathematics teaching, see in particular the contributions by R.MOSCHEO, *I Gesuiti e le matematiche nel secolo XVI. Maurolico, Clavio e l'esperienza siciliana*, Messina 1998, and by A. ROMANO, Il Messanense Collegium Prototypum Societatis Iesu, in *Gesuiti e università in Europa* (*secoli XVI - XVIII*), edited by G.P.BRIZZI, R.GRECI, Bologna 2002, 79-94.

structured in compendia. Such compendia were to be used in the teaching of the Collegium of Messina and, possibly, in every *Collegium* of the Society.

If one considers the chronology of Maurolico's writings, in the second half of the Sixties a significant increase of scientific activity can be registered, mainly oriented to the redaction of epitomes. In particular, in 1567 Maurolico wrote the Euclidean and astronomical compendia, which fell within the basic teaching of the Jesuit Universities (and not only). To be precise, in the early 1567, he completed the compendia of the first ten books of the *Elements* and reworked a text of some years earlier (1563), dedicated to stereometry, transforming it in the compendium of Books XI and XII. To conclude, he then wrote that the old edition of Books XIII-XV – the one dated 1532, to be clear – added to the most recent epitomes, would have finally completed the whole *Elementorum compendia*.

In April 1569, Maurolico vainly tried to advocate at the Superior General of the Society the publication of the compendia, emphasizing their general utility and need[7].

Unfortunately, the editorial project wrecked and the old mathematician, now seventy years old, had several writings left, ready for publication. The few extant documents, show that in this same period, precisely in 1570, Maurolico invested all his remaining energies in a new editorial operation, probably born from the ashes of the just faded one, which had to end, after many vicissitudes, with the publication of the *Opuscula mathematica*, which occurred in 1575, just few days after his death. Among the published opuscula, we find, surprisingly, the edition of Books XIII-XV of the *Elements*, without any trace of the remaining compendia.

The presence of the edition of the only Books XIII-XV and the subsequent exclusion of the compendia of the first twelve books, appears to be very astonishing, given the explicit will of Maurolico to avoid the separation of the compendia. The fact that his will has been disregarded would lead us to think that, unless some sudden rethinking of the author, there may have been some external interference, not yet identified, in the selection of the texts to be published in the *Opuscula*[8].

Concluding remarks

In 1528 Francesco Maurolico gave lessons on the *Elements*; in the same year, in the preface of his grammar textbook *Grammaticorum rudimentorum libelli sex*, he wrote to be ready to lay out a full scale programme for the renaissance of Greek mathematics. The first step of his ambitious plan was the restoration of the *Elements*, so to have a new edition *«ex traditione Maurolyci»* able to replace the worst printed editions. In the following years he reworked Books XIII-XV and in 1534, over a period of intense arrangement of his writings, he prepared a nearly final version of Book V and arithmetical books. Few years later he devoted himself to writing Book X.

The Maurolican editions of 1530's and 1540's essentially appear to be a critical merging of the traditions by Campanus and Zamberti; nevertheless, sometimes the author does not hesitate to replace Euclidean proofs with more easily intelligible ones (from his point of view, of course) or to add new propositions when he thinks incomplete the Euclidean theory. Although these writings are clearly not based on any kind of philological restoration of Euclid, they are not significantly far from the spirit of the *Elements*.

Unfortunately, at this time we are unable to establish whether the editions of the 'missing' books of the *Elements* –i.e. Books I, III, IV, VI, XI and XII– are lost, nor to categorically exclude that they have never been written. Anyway, we can say, with a certain validity, that the Euclidean edition of the years 1532-1541, although limited to few books, is not, as might appear at first sight, an unused work set aside until a future completion. Maurolico, in fact, considered and used these writings the same way as a real edition of the Euclidean work, far superior to those available concerning what regards mathematical rigour and completeness of treatment. To take an amazing example, in his *Arithmeticorum libri duo* (printed posthumously in 1575 together with *Opuscula Mathematica*) Maurolico sometimes cites Euclidean propositions existing only in his edition *«ex traditione Maurolyci»* of the Thirties.

While the drafts of the Thirties follow in the wake of existing Euclidean traditions, the successive compendia of the Sixties are not only a reasoned synthesis of the *Elements*, because they are completely influenced by a deep arithmetical interpretation of the topics, from the theory of proportions to the relationships between regular polyhedra. Following this peculiar approach, Maurolico often chooses to replace, where possible, geometrical proofs with arithmetical ones. The compendia of the fifteen books of the *Elements* –grouped on the basis of the autograph instructions left by Maurolico– show tracts of deep originality, but at the same time they constitute a very heterogeneous work, as their complex genesis testifies.

[7] See P.D'ALESSANDRO, P.D.NAPOLITANI I primi contatti fra Maurolico e Clavio: una nuova edizione della lettera di Francesco Maurolico a Francisco Borgia, *Nuncius*, 16 (2001), pp. 511-522.

[8] In this regard, we would remember that Rosario Moscheo has highlighted the role played by the Jesuit Vincenzo Le Noci in promoting the publishing venture culminated in the print of the *Opuscula* (MOSCHEO, *I Gesuiti e le matematiche…*, p.221 and following). It is plausible that Le Noci may have influenced Maurolico also in the choice of the writings to be published.

The edition of Books XIII-XV, for example, seems to adhere more to the editorial criteria of the Euclidean project of the Thirties, rather than to the style of the compendia of the Sixties.

The Euclidean writings as a whole, set different kind of problems: although the textual tradition is rather poor, the edition of these works has to include partial redactions of the *Elements «ex traditione Maurolyci»*, compendia written on different periods and many related fragments. The difficulty of placing such different texts into a coherent framework does not only regard the editorial aspect, but also and especially the interpretative one. The crucial points are, first of all, a reliable reconstruction of the two different Euclidean projects undertaken by Maurolico, and a precise evaluation of the actual influence of the Euclidean edition on his scientific production, especially concerning the close relations existing among arithmetical and Euclidean writings.

The first step to reach this aim is the critical edition of the Euclidean texts, which will be published within the National Edition of Maurolico's mathematical works (*Francisci Maurolyci Opera Mathematica*); anyway, a first transcription of such texts is available in the website of the *Progetto Maurolico* (*www.maurolico.unipi.it*).

PLAYFAIR'S *GEOMETRY* CROSSES THE MEDITERRANEAN: TRANSLATION OF AN ENGLISH GEOMETRY TEXTBOOK INTO ARABIC

Gregg DE YOUNG
Department of Mathematics and Actuarial Science
The American University in Cairo, EGYPT
gdeyoung@aucegypt.edu

Abstract

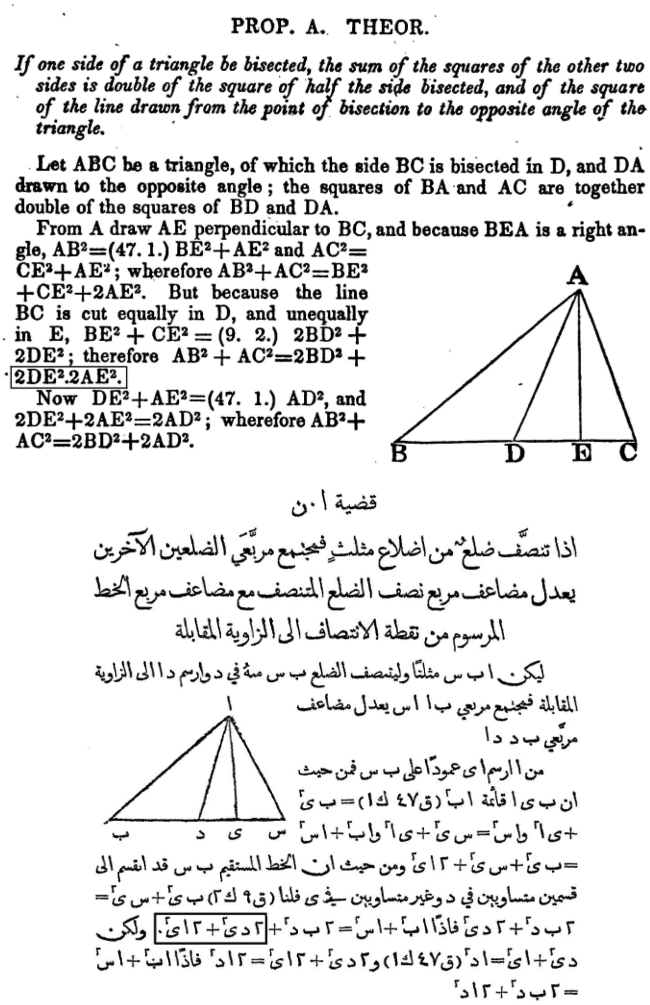
Cornelius Van Alen Van Dyck (1818-1895), best known as a translator of the Bible into Arabic, also translated or wrote numerous Arabic textbooks on mathematics and the natural sciences. In this paper we examine his translation of Playfair's Elements of Geometry *into Arabic. We describe some of the interesting features of the translation itself and offer suggestions why Van Dyck chose to translate this textbook.*

The *Elements of Geometry* was John Playfair's first major publication (1795). A half-century after it appeared, it traveled across the Mediterranean to appear in a very different cultural and linguistic context – a classic example of knowledge in motion. Before it appeared in Arabic form, the text had already traveled considerably. It proved immediately popular in Britain (13 editions before mid-century) and even more popular in America (some 33 editions and printings, not including summaries, extracts, and further re-workings).[1] In this paper we shall focus on the transmission of this classic of Anglo-American mathematics pedagogy into Arabic.

John Playfair (1748-1819) is better known today for his explanation of Hutton's essay on the geological history of the earth. He had, however, developed an interest in mathematics and mathematics education very early in life. His mathematical talents were widely acknowledged when, at age 18, he competed (unsuccessfully) for the chair of mathematics at Marischal College, Aberdeen. He finally acquired a formal academic position, becoming joint professor of mathematics (together with Adam Ferguson) at Edinburgh University in 1785. No doubt it was from his own pedagogical experience that he wrote his textbook. Throughout his life he also wrote reviews of mathematical works, mostly originating from outside England, for the *Edinburgh Review*.

[1] See A. Ackerberg-Hastings, "Analysis and Synthesis in John Playfair's *Elements of Geometry*," *British Journal for History of Science* 35 (2002), 43-72 (page 43, note 1).

Playfair made no claim of originality for his textbook. His *Geometry* was admittedly based directly on the classic *Elements of Euclid* of fellow Scots mathematician, Robert Simson (1687-1768).[2] Playfair's justification for producing a new introduction to Euclid was that the scholarship displayed in Simson's text made it not easily understandable to beginning students in mathematics.[3] Playfair's goal was to produce a text more readily accessible to students. In his introduction, he mentioned only two innovations that he had introduced: (1) he used "algebraic notation" to express the arguments in book V of the *Elements* which discusses ratios of magnitudes (Figure 1)[4] and (2) he substituted a new axiom ("Playfair's Axiom") in place of Euclid's perennially criticized parallel lines postulate.[5]



PROP. A. THEOR.

If one side of a triangle be bisected, the sum of the squares of the other two sides is double of the square of half the side bisected, and of the square of the line drawn from the point of bisection to the opposite angle of the triangle.

Let ABC be a triangle, of which the side BC is bisected in D, and DA drawn to the opposite angle; the squares of BA and AC are together double of the squares of BD and DA.

From A draw AE perpendicular to BC, and because BEA is a right angle, $AB^2=$(47. 1.) BE^2+AE^2 and $AC^2=CE^2+AE^2$; wherefore $AB^2+AC^2=BE^2+CE^2+2AE^2$. But because the line BC is cut equally in D, and unequally in E, $BE^2+CE^2=$(9. 2.) $2BD^2+2DE^2$; therefore $AB^2+AC^2=2BD^2+$ $2DE^2.2AE^2.$

Now $DE^2+AE^2=$(47. 1.) AD^2, and $2DE^2+2AE^2=2AD^2$; wherefore $AB^2+AC^2=2BD^2+2AD^2$.

Fig. 1: Top: Playfair's use of "algebraic notation" in added proposition A of book II. J. Playfair, *Elements of Geometry* (New York: W. E. Dean, 1846), p. 59. A typesetting error, recurring in several editions, is highlighted by a box. The error is found in multiple editions. Bottom: Van Dyck translation of the proposition. C. Van Dyck, *Kitāb fī Uşū al-Handasa* (Beirut, [1857]), p. 68. Van Dyck has corrected the typesetting error. This translation is an early example of algebraic notation in Arabic typesetting.

[2] R. Simson, *The Elements of Euclid, viz. The First Six Books, together with the Eleventh and Twelfth*, (Edinburgh: J. Balfour, First edition, 1756; Sixth edition, 1781).

[3] Despite its uncompromising erudition, Simson's treatise was remarkably popular as a textbook –some 26 editions in Britain– and had been translated into Portuguese, Spanish, French, and German. See Ackerberg-Hastings, "Analysis and Synthesis," pp. 47-48.

[4] This claim is not correct. Similar notation had been used as early as Isaac Barrow's 1660 edition. See J. Barrow-Goodman, " 'Much necessary for all sortes of men': 450 Years of Euclid's Elements in English," *Bulletin of the British Society for History of Mathematics* 21 (2006): 2-25 (p. 19, figure 12).

[5] This axiom states: Two straight lines that intersect one another cannot both be parallel to the same straight line. It had been known since the time of Proclus, and Playfair made no claim of originality. Nevertheless, the formulation has now become known by his name.

The translation of Playfair's *Elements of Geometry* into Arabic was the work of American missionary, Cornelius van Alan van Dyck (1818-1895).[6] Although he received limited formal schooling, he enrolled in Jefferson Medical College (Philadelphia), receiving his degree in 1839. Moved by the winds of religious revival sweeping New England, he enlisted as a missionary and was dispatched in 1840 to serve in the Ottoman province of Syria (comprising most of what are today the nations of Syria, Lebanon, Jordan, and Israel) under the auspices of the American Board of Commissioners for Foreign Missions (ABCFM). He spent the rest of his career in Syria. He quickly revealed exceptional talent in both written and spoken Arabic. Today his name is associated with the translation of the King James Bible into Arabic. The bulk of his oeuvre in Arabic, though, was a series of science textbooks: geography (1852), algebra (1853), geometry (1857), chemistry (1869), logarithms (1873) and logarithmic tables (1873), astronomy (1874) and history of astronomy (1874), as well as a medical textbook on pathology (1878), all expounding the modern European scientific tradition.

When Van Dyck produced his translation of Playfair's *Geometry*, the Arabic-reading world already had a tradition of discussion of Euclidean geometry dating back almost 1000 years. This tradition employed a well established technical vocabulary and formulaic structure. When he made his translation of Playfair's *Geometry*, however, Van Dyck ignored this tradition and instead used vocabulary and discourse styles taken directly from Playfair's English treatise. A few examples, shown in Table 1, will suffice to illustrate the situation.

Table 1: Examples of non-traditional terminology used by Van Dyck in his translation. In most cases, his choice of vocabulary can be explained as a literal word-for-word substitution of Arabic terms for Playfair's mathematical terms.

Traditional		**Van Dyck**	
	book / independent sub-unit		book / codex
	geometrical proposition		proposition / legal principle
	conversely		reversal / inversion
	Another demonstration		"Otherwise"

Not only did Van Dyck face decisions about whether to use traditional mathematical vocabulary or to coin new terminology, he also was called upon to decide which Arabic letters to use to represent the letter labels used in geometric diagrams to identify points, line segments, areas, etc. In the Arabic Euclidean tradition, these labels were usually assigned following the *abjad* order of the letters of the alphabet.[7] One option that Van Dyck might have chosen would be to replace Playfair's English letters with their corresponding equivalents in the Arabic alphabet. Another option might have been to replace Playfair's letters with the corresponding letters from the *abjad* sequence. Van Dyck, however, did neither. Instead, he often used a more-or-less phonetic system. For example, Playfair's letter C was replaced in Van Dyck's Arabic by the letter whose name sounds like the English word "seen". Similarly, Playfair's letter E became, for Van Dyck, the Arabic letter , which functions very often like the letter Y in English and, when used as a vowel, sounds like the Y in the English word "really" (Fig. 1). The situation is complex, though, for Van Dyck decided to replace Playfair's letter I with the Arabic letter ("meem"), the phonetic equivalent of M and he never used the Arabic letter to transliterate its phonetic equivalent Z.

Van Dyck tended to copy Playfair's diagrams exactly, although we might have expected him to use mirror images. Since Arabic is read from right to left, the labels on the Arabic diagrams are now in an unnatural order (Fig. 1). A native reader of Arabic would certainly have found this arrangement odd, if not actually awkward. But Van Dyck evidently wished to remain as close as possible to a reproduction of the diagrams in Playfair's treatise.

Despite his over-all tendency toward literal translation, Van Dyck was willing on several occasions to alter the text of Playfair.[8] For example, he modifies the verbal statements of several definitions of book I. The first two definitions are given by Playfair as:

---

[6] Almost the only source of information on Van Dyck's life is L. Sa'di, "Al-Hakîm Cornelius Van Alen Van Dyck (1818-1895)," *Isis*, 27 (1936): 20-45.

[7] *Abjad* ordering differs from lexical order. It may be derived from Greek alphabetic numerals.

[8] It is possible that Van Dyck is literally translating an edited version of Playfair's textbook. In the absence of explicit evidence, however, I attribute the alterations to Van Dyck.

1. A point is that which has position but not magnitude.
2. A line is length without breadth.

These definitions were rendered by Van Dyck as:

-

-

Translating these statements literally into English, we have:

1. The point is something that has position only *and does not have length or width or height*.
2. The line is length without breadth *or height*.

We see that in both definitions Van Dyck has added to the statement of Playfair the phrases indicated in italic text. These additions don't change the meaning of Playfair's definitions, but they do diverge from the strictly literal word-for-word translation that Van Dyck often seems to favor. It is not clear why Van Dyck thought it best to add additional explanation to Playfair's original statement.

Definition 3 illustrates another kind of modification to Playfair's text. Playfair's statement reads: "If two lines are such that they cannot coincide in any two points, without coinciding altogether, each of them is called a straight line."

Van Dyck renders this statement into Arabic as:

Translating this definition literally into English we have: "Two lines that do not coincide in two of their points unless they coincide in all are called straight. *And one may also say that the straight line is the shortest distance between two points*."

In this case, Van Dyck has added an alternate definition, indicated in italic type, that does not appear in Playfair's text. Where did it come from? I believe that the most probable source is Legendre's introduction to geometry.[9] He formulates his definition as: "La ligne droite est le plus court chemin d'un point a un autre." Why Van Dyck decided to add this alternative form of the definition we may never know.

Other changes are also occasionally introduced into Van Dyck's translation. On a few occasions, he has altered the labeling of the diagrams of Playfair (figure 2). On another occasion, Van Dyck substituted a different proof for one of Playfair's propositions (figure 3).

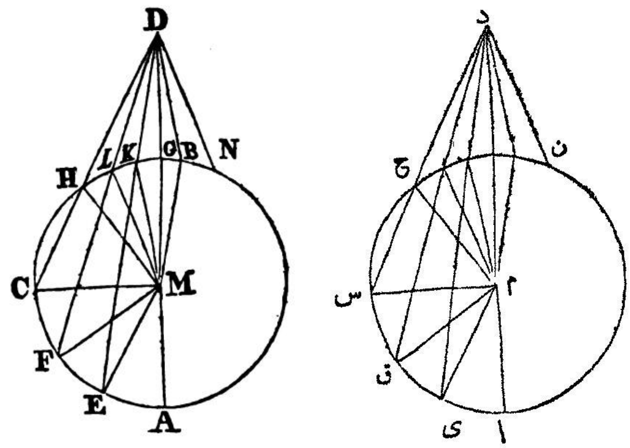

Fig. 2: Diagrams for proposition III, 8. Left: from J. Playfair, *Elements of Geometry* (New York: W. E. Dean, 1946, p. 67. Right: C. Van Dyck, *Kitāb fī Uşūl al-Handasa* (Beirut, [1857]), p. 77. Whether this simplification in the Arabic diagram was done by Van Dyck or his printer is unknown.

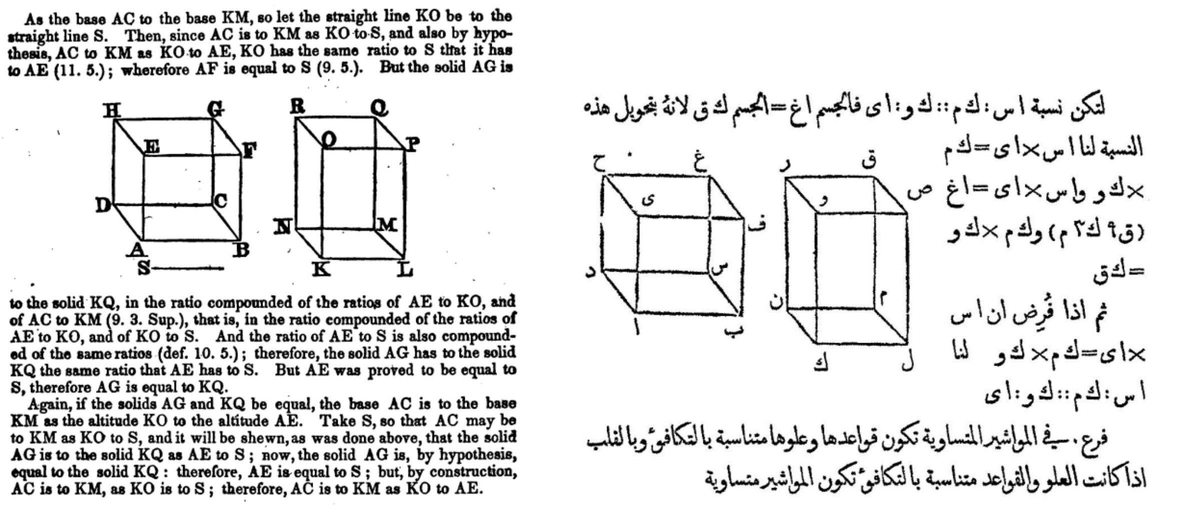
[9] A. M. Legendre, *Élements de géométrie*, septieme édition (Paris: Didot, 1807), p. 1.



As the base AC to the base KM, so let the straight line KO be to the straight line S. Then, since AC is to KM as KO to S, and also by hypothesis, AC to KM as KO to AE, KO has the same ratio to S that it has to AE (11. 5.); wherefore AF is equal to S (9. 5.). But the solid AG is to the solid KQ, in the ratio compounded of the ratios of AE to KO, and of AC to KM (9. 3. Sup.), that is, in the ratio compounded of the ratios of AE to KO, and of KO to S. And the ratio of AE to S is also compounded of the same ratios (def. 10. 5.); therefore, the solid AG has to the solid KQ the same ratio that AE has to S. But AE was proved to be equal to S, therefore AG is equal to KQ.

Again, if the solids AG and KQ be equal, the base AC is to the base KM as the altitude KO to the altitude AE. Take S, so that AC may be to KM as KO to S, and it will be shewn, as was done above, that the solid AG is to the solid KQ as AE to S; now, the solid AG is, by hypothesis, equal to the solid KQ: therefore, AE is equal to S; but, by construction, AC is to KM, as KO is to S; therefore, AC is to KM as KO to AE.

لتكن نسبة ا س : ك م :: ك و : ا ى فالجسم ا غ = الجسم ك ق لانهُ بتحويل هذه النسبة لنا ا س × ا ى = ك م × ك و و ا س × ا ى = ا غ (ق ٩ ك ٣ م) و ك م × ك و = ك ق

ثم اذا فُرِض ان ا س × ا ى = ك م × ك و لنا ا س : ك م :: ك و : ا ى

فرع . في المواشير المتساوية تكون قواعدها وعلوها متناسبة بالتكافؤ وبالقلب اذا كانت العلو والقواعد متناسبة بالتكافؤ تكون المواشير متساوية

Fig. 3: Top: The demonstration for proposition 10 of Supplement III from J. Playfair, *Elements of Geometry* (New York: W. E. Dean, 1846), p. 206. Bottom: the demonstration from C. Van Dyck, *Kitāb fī Uşūl al-Handasa* (Beirut, [1857]), p. 237. The differences are not purely cosmetic by substituting algebraic notation. The demonstration itself has been altered. Van Dyck no longer needs line S found in Playfair's diagram, so it is omitted.

In sum, Van Dyck produced a fairly literal translation of Playfair's text for his students. He did make a few modifications, but these changes are more noteworthy for their infrequency than for their impact on the mathematics of the treatise. But what motivated his effort? Since the traditional introductory text in Euclidean geometry, the *Tahrīr Kitāb al-Uşūl* of Naşīr al-Dīn al-Ţūsī had already been printed in Istanbul in 1801, why did Van Duck feel it necessary to translate a European introduction to Euclidean geometry? Was it simply a matter of the earlier printed version being out of print? But if there were strong demand for the printed version, it is difficult to imagine that this demand would not soon be translated into new printings. Or was the printed edition simply not available in Syria? Again, it seems unlikely that demand for the treatise would not produce an increased importation of the book.

Van Dyck has told us little about the rationale for his translation efforts. The brief author's preface to the translation of Playfair mentions only a perceived need for a textbook on Euclidean geometry. As rationale for choosing Playfair, Van Dyck's brief introduction says only that Playfair made some improvements (which are not described) in the restoration of the text originally produced by Simson. These brief sentences, although they may be accurate enough, provide very little concrete information. Perhaps an examination of Van Dyck's life and work against the broader context of the Protestant missionary endeavor in 19th century Syria will shed some light on his science translation activity, his choice of Playfair as the text to translate, and some of the unusual choices of mathematical vocabulary and related architectural features.

The Protestant mission station of the ABCFM in Ottoman Syria where Van Dyck spent most of his working life was only one local manifestation of a world-wide mission movement that arose in Protestantism early in the 19th century. At least two streams of thought converged in this mission movement. One was an intent to bring cultural reform and the benefits of Christian society to parts of the world perceived by the missionaries as "backward" socially and politically. This emphasis grew out of an early form of social gospel. Its advocates pursued social reforms as a means to improve the physical lives of people so that they would be more open to the call of the gospel to repent and reform their spiritual lives.

The second strand was an outgrowth of the rising pre-millenial interpretation of Scripture, a sense that the history of the present age was coming to completion and that Protestantism was poised to announce the end of the reign of "false religions" and to prepare for the coming reign of Christ on earth. "Prophecy, history, and the present state of the world seem to unite in declaring that the great pillars of the Papal and Mahommedan impostures are now tottering to their fall... Now is the time for the followers of Christ to come forward boldly and engage earnestly in the great work of enlightening and reforming mankind."[10]

---

[10] J. Morse, S. Worcester & J. Evarts, "Address to the Christian Public, November 1811," in the *First Ten Annual Reports of the American Board of Commissioners for Foreign Missions* (Boston: Crocker and Brewster, 1834), p. 28. The passage is quoted in M. Elshakry, "The Gospel of Science and American Evangelism in Late Ottoman Beirut," *Past and Present* 196 (2007), p. 174.

Van Dyck's translations can be seen as an integral part of the missionary strategy of the ABCFM outpost in Syria. When direct conversion proved difficult to effect, the missionaries began to turn to indirect methods that might lead to the desired conversions.[11] One of the more effective strategies was to create schools to teach the modern scientific theories that had been developed in Europe. This strategy was partially successful – it attracted many students into mission schools where they were exposed to mandatory religious instruction and required to attend at religious services and prayers.[12] As one missionary report was to remark, they were sometimes "obliged to bait the hook with arithmetic" although in a few cases "God's word was a sufficient charm in itself" to draw students into these schools.[13]

The mission schools very often emphasized the sciences as well as religious instruction. The emphasis on science was two-fold. On one level, the goal was simply to attract students into the schools where they could then be introduced to Protestant religious instruction. But on another level, the sciences were also emphasized as a way toward God in their own right. The sciences offered a multiplicity of metaphors and analogies to instill in students a desire for the divine. A scientific understanding of nature encouraged a sense of religious awe and wonder. Moreover, the use of rational argument to win assent in a scientific debate encouraged the hope that religious converts might be won through similar tactics.[14]

These mission schools grew rapidly and became quite successful, attracting many students. Despite all their efforts, though, there were still very few conversions in the sense that individuals explicitly changed their ecclesiastical affiliation. Although the ABCFM governing board became increasingly unhappy about the expense of the Syrian mission in relation to the number of converts produced, the missionaries forged ahead, ever hopeful that, with continued effort, their labor might begin to bear the spiritual fruits both they and their financial supporters desired.

But if you are planning to teach modern scientific studies, you will need appropriate textbooks, and there were none available in Arabic. One solution, of course, was to force the students to learn English. As the missionaries had noted already in 1837, "We have endeavored to advance [the students in our school] as rapidly as possible in the acquisition of our language… Without a knowledge of English, it would be impossible to give them a thorough education, as there are no suitable elementary books in Arabic."[15] It was to remedy this lack of appropriate textbooks that Van Dyck devoted his considerable skill as a linguist and translator. In this paper, we have restricted our focus to his translation of Playfair's *Geometry*. And so we return to the question asked earlier: why Playfair, when traditional Arabic introductions to Euclid were widely available both in print and in manuscript?

I shall suggest several possible reasons. First, Playfair's text had been introduced into the United States as early as 1806 and proved at least as popular in that context as in Britain. There were more than thirty American editions and reprintings of the text during Van Dyck's lifetime.[16] These American editions were produced mainly in New York or Philadelphia. And since Van Dyck grew up in upstate New York and received his medical training in Philadelphia, it is tempting to imagine that he might well have used Playfair's treatise in his own education. Moreover the treatise was deserving of its popularity, for Playfair was both an educator and a skillful expositor with an easy style of presentation that made his work exceptionally accessible to students.

Moreover, Playfair had been associated with many of the leading luminaries of the Scottish Enlightenment in Edinburgh. These men focused attention on geometry as a key part of education. Through study of geometry, students would be exposed to the processes of right reasoning so necessary to any educated person. Geometry fit well with the Scottish (and American) penchant for the practical and a conscious focus on the common sense interpretation of human experience. Under Scottish leadership, instruction in geometry began to change from rote memorization of results to study of the proofs and argumentation of Euclid. If the mandate of education was to develop the moral sense of the citizen, geometry was widely perceived as an essential tool for it taught right reasoning on which moral life was built.

The tie between Scotland and American higher education had been close since the early years of the eighteenth century. The ideas of the Scottish Common Sense school infused American classrooms both by way of Scots professors and through textbooks published by Scottish authors. From these roots came the emphasis on liberal arts education with a practical bent that increasingly characterized American curricula. Seen against this backdrop, the popularity of Playfair's textbook in America is easy to understand. Not only is it a masterful exposition of Euclid, but it came to American classrooms

already infused with ideals that meshed almost seamlessly with the rising American interest in practical and liberal arts education.

The choice of Playfair to translate also fits well with this pattern. Not only was Van Dyck an American, he was also a Protestant missionary intent to spread the gospel both in a theological sense and in a cultural sense. Hence his desire to provide a form of liberal arts education in Syria, culminating in the establishing of the Syrian Protestant College (later to become the American University of Beirut). Mathematics played a key role in this liberal arts education, since it was the key by which students learned to think clearly and systematically. Developing the reasoning skill through mathematics would permit students not only to perceive the errors of "false" religion (whether Catholicism or Islam) but also would encourage an enlightened and critical view of the "decadent" social system of the crumbling Ottoman state.

Van Dyck's translation often appears excessively literal, with choices in translation and "architecture" that seem calculated to repel the reader familiar with the more traditional Arabic discourse on Euclidean geometry. I suggest that these choices may well have been deliberate and conscious, a way to distance Playfair's approach, based on Common Sense ideals, from the more traditional study of Euclid. Van Dyck's translation is a transplanting of Playfair into a different cultural milieu in the hopes that the new mathematics would take root and lead ultimately to the production of a new citizenry prepared to take the lead in reforming Syrian society, reshaping it to become more like the Puritan Protestant society of New England. Although the hope that modern mathematics would translate into spiritual renewal was rarely realized, Van Dyck's works did contribute, at least indirectly, to the Arab intellectual revival of the 1880s.

STUDIES ON THE PROBLEM OF MINIMUM AND MAXIMUM IN CONIC SECTIONS' TRADITIONS. APOLLONIOS OF PERGA AND SERENOS OF ANTINOEIA

Konstantinos NIKOLANTONAKIS
University of Western Macedonia, GREECE
nikolantonakis@noesis.edu.gr

Abstract

The treatise of Apollonios of Perga Conics *has put its sign on the development of mathematical sciences in the Arabic world since the 9th century and Apollonios is the most referenced and studied mathematician after Euclid. The Arabic translation of the 7 books of the* Conics *has been done in Baghdad in the 9th century, after the demand of Banu Musa from Hilal ibn Hilal al-Himsi and has been controlled by Thabit Ibn Qurra. This translation has inaugurated a tradition, and has influenced the interest on solid problems –especially the trisection of an angle and the construction of a regular heptagone– the application of the conics on problems from other fields like the optics (burning mirrors and lenses), geometric resolution of the 3rd degree equations (works of Al-Khayyam and Sharaf al-Din al-Tusi) or even the theory of astrolabes, sun clocks or the perfect compass. All these applications will lead to the reinvention of new properties on these curves – focus properties, study of asymptotes, local and harmonic properties. In the 5th book of the* Conics *which survived only in Arabic, Apollonios studies the problem of minimum and maximum. The treatise* Section of a Cone *of Serenos of Antinoeia (4th century A.C.) deals with the areas of triangular sections of right or scalene cones made by planes passing through the vertex and either through the axis or not through the axis, showing when the area of a certain triangle of a particular class is a maximum, under what conditions two triangles of a class may be equal in area.*
In the context of this paper we are going to present a comparative study of these two treatises and show the influence of the work of Apollonios on the level of some enunciations to the approach of Serenos.

Division of the treatise *On the Section of a Cone*

Serenos of Antinoeia is the author of two mathematical treatises *On the section of a cylinder* and *On the section of a cone* that the manuscript tradition transmitted to us following the first four books of *The Conics* of Apollonios from Perga. This article provides an outline on the content of the treatise *On the Section of a Cone* where Serenos is doing a comparative study on the sections produced in a right or an oblique cone by plans passing by its vertex. We identify, classify and study the different problems Serenos treats in the three sections of his treatise. The treatise of *On the Section of the cone* of Serenos can be divided in three relatively independent parts. In the first part, propositions 1-14, he works on the right cones; in the second, propositions 15-57, he works on the oblique cones. The last propositions 58-69, constitutes a separate section where he looks at the relationship between volumes of two right cones in relation to the heights, the bases and the surfaces of the triangular sections which pass by their axis (Heath; 522). In each part Serenos poses several problems and gives their solution We will also try a first attempt to find relations between this treatise of Serenos and the Book V of *The Conics* of Apollonios of Perga.

Lemmas in the treatise *On the Section of a Cone*

We should underlie a big amount of auxiliary lemmas (propositions 1, 2, 17, 18, 19, 21, 33, 37-39, 52, 53, 54, 55, 56) the majority of which were used several times to solve various problems that Serenos posed in this treatise. Others are put in the treatise to serve only once in the demonstration of a proposition.

First part of the treatise *On the Section of a Cone*: the case of right cones

In this part of his work we notice the existence of several theorems and problems by which Serenos tries to resolve three different problems that we can gather in the following way.

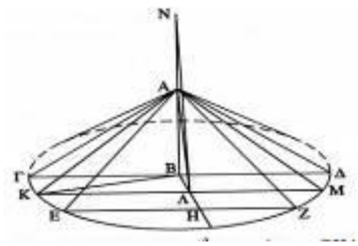
In the first problem (propositions 5 and 8) he shows that if the axis of the cone is not smaller than the radius of the base, the axial triangle is the greatest among those which are determined in this cone and conversely (Heiberg; 126-128 and 134-136). Proposition 6 (Heiberg; 128-132) is the generalization of 5. In proposition 6, he builds the bases of nonparallel triangles (in the demonstration of prop. 5 the bases are parallel) between them and which meet in a certain point.

The triangle ΑΓΔ is bigger than the triangle AEZ (prop.5).

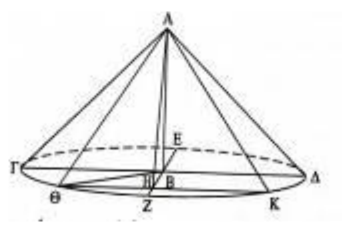
The triangle ΑΓΔ is bigger than the triangle ΑΖΔ (prop.6).

In the second problem he shows initially that if two plans carried out by the vertex, one passing by the axis, the other out of the axis, determines triangles whose surfaces are equivalent, the cone is obtuse-angled, i.e. the axis of the cone will be smaller than the radius of its base (propositions 10 and 12). Proposition 12 (Heiberg; 142-144) gives us the construction which Serenos needs in the demonstration of proposition 10 (Heiberg; 138-140).

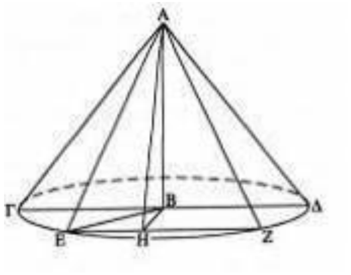
In proposition 11 (Heiberg; 140-142), he also shows that any plan, carried out by the vertex, between the two plans of equivalent triangles determines a triangle bigger than these equivalent triangles. We can notice that in this case (propositions 10-12) the problem takes the following form: "To cut an obtuse-angled cone with axis smaller than the radius, so that the triangular section obtained is either equal to an axial section (proposition 12) or it will be maximum (proposition 11)".



Triangle AKM is bigger than triangles ΑΓΔ and AEZ (prop.11).

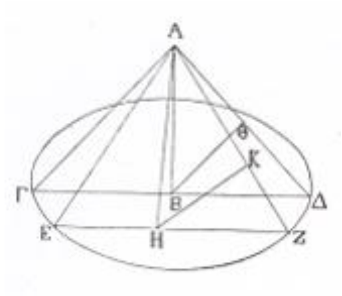


Triangle ΑΓΔ is equivalent with the triangle ΑΘΚ (prop.12).



The axis AB is smaller than the radius BΔ if AΓΔ is equivalent to ABZ (prop.10).

In the third problem, proposition 13 (Heiberg; 144-148) and proposition 14 (Heiberg; 148-150) he shows that, in the obtuse-angled right cone the triangle determined by a plan passing by the vertex is maximum then its height is equal to half of its base, i.e. with the radius.



Triangle AΓΔ is bigger than all the non similar triangles established in the cone if height equals radius (prop.13).

In the first part Serenos noticed a significant difference in behavior between the acute-angled and obtuse-angled right cones, or as he prefers to state, between the cones whose axis h is major the radius r of the base and those of which it is minor.

In this part he obtains the following results:

If the axis is smaller than the radius of the base, the intermediate triangle is bigger than the other triangles (proposition 11).

If the axis is equal to the radius, the axial triangle is bigger than all the non similar triangles (proposition 13).

If the axis is bigger than the radius, the axial triangle is bigger than all the triangles determined in the cone (proposition 5 and 6).

Second part of the treatise *On the Section of a Cone*: the case of oblique cones

In the second part of *On the Section of the cone* (propositions 15-57) Serenos considers the oblique cones and compares the triangular sections of one of the following three kinds with other sections of the same kind by considering their surfaces.

The three kinds of the triangular sections are (Heath; 523):

1. the axial section, which contains all the sections passing by the axis.
2. the isosceles section, which contains the sections in which bases are perpendicular to the projection of the axis of the cone on the plane of the base.

3. the parallel section, which contains triangular sections whose bases are (a) the diameter of the circular base which passes by the foot of the perpendicular by the vertex of the plane of the base and (b) the chords of the circular base which are parallel to this diameter.

In this part, Serenos, as in the first part, poses also several problems which he gathers and he tries to find a response to each one of these problems. In the following, we will examine each problem separately.

Problem 1

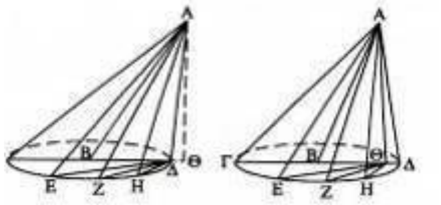


Fig. 1.

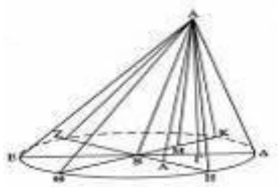

Fig. 2.

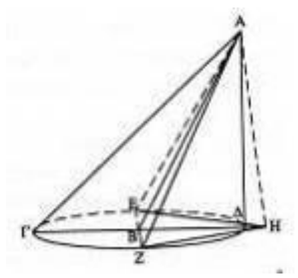
In proposition 16 (Heiberg; 152-156) Serenos demonstrates that the line ΑΓ will be maximum and the line ΑΔ will be minimum and among the other lines, that which is brought closer to the greatest will be bigger than that which is the most distant.

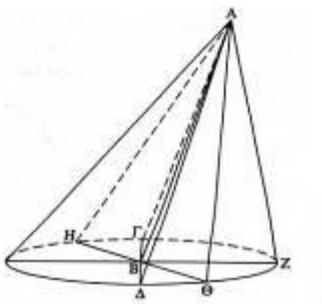
Problem 2

In propositions 22 and 23 (Heiberg; 170-172), the axial sections which have their bases perpendicular to the line ΓΔ (diameter of the circle of the base) are isosceles.



Triangle AEZ is isosceles (prop.22).

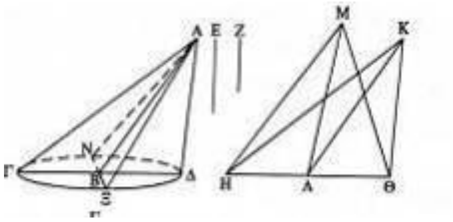
Problem 3



In proposition 24 (Heiberg; 172-176) he demonstrates that the isosceles triangle ΑΓΔ is the maximum (μέγιστον) of all the triangles which pass by the axis, and the triangle AEZ, perpendicular on the plane of the base is the minimum (ελάχιστον).

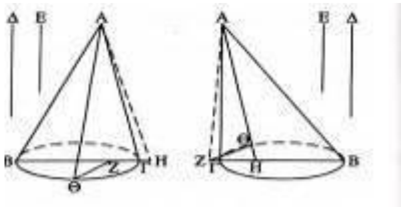
The formulation of this proposition resembles that of proposition 16. In proposition 16 Serenos finds the maximum and minimum lines, while in proposition 24 he uses this property to find the maximum and minimum triangles. Indeed, we can say that in proposition 16 he seeks the maximum side and in proposition 24 he seeks the maximum triangle.

Problem 4



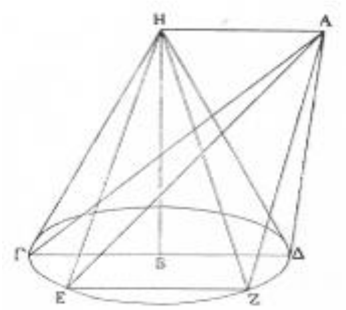
His efforts, in proposition 27 (Heiberg; 182-188) are focused on the construction of the triangle ANΞ so that to be to the triangle AΓΔ in the ratio of the line E to the line Z.

Problem 5



In proposition 25 (Heiberg; 176-178) he is trying to construct a segment AΘ that is to segment BA as Δ/E (Δ/E = BA/AH = BA/AΘ).

Problem 6



In proposition 29 (Heiberg; 188-192) Serenos took the third kind of the sections with bases parallels to diameter.

If perpendicular AΔ is not smaller than radius, the maximum triangle AΓΔ is that which is perpendicular to the base of the cone and is bigger than all those who have their bases parallel to ΓΔ.

In proposition 30 (Heiberg; 192) he demonstrates the property: If perpendicular is smaller than radius, the triangle AΓΔ in question is not the maximum of the triangles.

In these two propositions, Serenos examines for bases parallel to the diameter, the two different cases:

1. height > = radius.
2. height< radius.

and he concludes that:

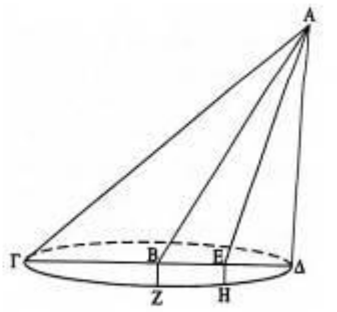
1. If triangle HΓΔ< triangle HEZ, then triangle AΓΔ< triangle AEZ.
2. If triangle HΓΔ> triangle HEZ, then triangle AΓΔ> triangle AEZ.
3. (3) If triangle HΓΔ= triangle HEZ, then triangle AΓΔ= triangle AEZ.

Serenos, in the following propositions, works on the isosceles section which passes by the axis.

We can thus distinguish the following problems which concern the isosceles sections.

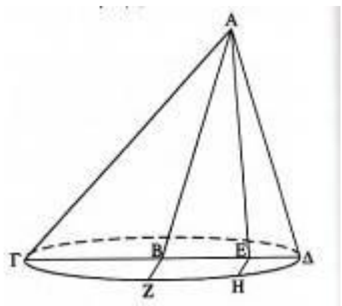
Problem 7

In proposition 31 (Heiberg; 192-194) he states that if axis is bigger than the radius or equal to the radius, the isosceles axial triangle is the maximum among all isosceles triangles established on the side where the axis is inclined. He establishes proposition 32 (Heiberg; 196-198) to examine the same problem but for the case where the axis a is smaller than the radius r.



The isosceles triangle carried out by the line AB is the biggest of the given isosceles triangles having their bases located between the points B and Δ.

Problem 8

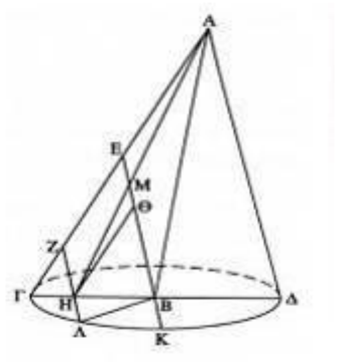


In proposition 34 (Heiberg; 200) he stresses the property: if the isosceles triangle AE, EH is equivalent with the isosceles triangle from AB, BZ then EA > AB.

In the following proposition 35 (Heiberg; 200-204) he demonstrates one problem of the same kind: if the isosceles triangle AE, EH is equivalent with the isosceles triangle from AB, BZ then AB < BΔ.

Problem 9

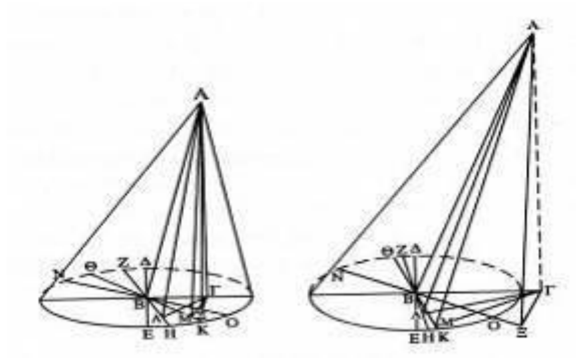
The ninth problem of the treatise *On the Section of a Cone* is demonstrated in the context of propositions 36 and 40-44 (Heiberg; 206-208 and 216-230): If, in an oblique cone, isosceles triangles are established on parallel bases on the side where the axis is inclined, the isosceles triangle passing by the axis will be neither biggest nor smallest of all the isosceles triangles.



The isosceles triangle passing by the axis is not the smallest of all the isosceles triangles which have their bases between the points Γ and B.

Problem 10

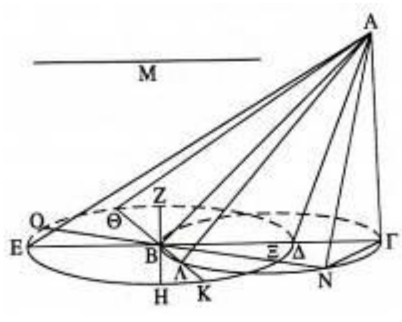
It is also very interesting the problem in proposition 45 (Heiberg; 230-234) in which Serenos shows that the place of orthogonal projections of the perpendiculars of an oblique cone on the diameters of the base is a circumference of only one circle, located in the same plane with the base of the cone and described around the diameter consisted by the cut out line, in this plan, between the center of the base and the perpendicular carried out of the vertex on this plane.



The points B, Λ, M are located on the circumference of only one circle whose diameter is the line BΓ.

Problem 11

In proposition 47 (Heiberg; 236-242) he examines the following problem: "being given in an oblique cone one of the triangles passing by the axis which is neither the greater nor the smaller, to find another triangle passing by the axis which, jointly with the triangle given, is equivalent with the sum of the biggest and the smallest of the triangles passing by the axis".

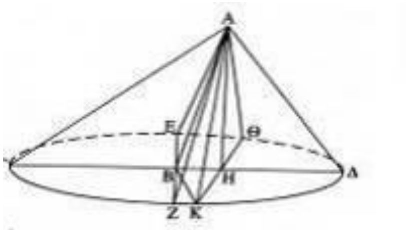


Triangle ΘAK + triangle OAΞ = triangle ZAH + triangle EAΔ.

Where ΘAK is the triangle passing by the axis, ZAH is the maximum triangle, EAΔ is the minimum triangle and OAΞ is the triangle searched.

Problem 12

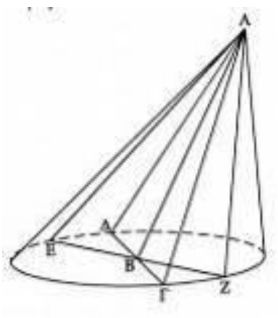
In proposition 50 (Heiberg; 246-248) Serenos demonstrates that: If the axis is equal the radius, then to construct the following ratio EAZ / ΓAΔ = ΓAΔ / ΘAK.



Where the triangle ΓΑΔ which is the minimum triangle of those passing by the axis, will be to the isosceles triangle ΘΑΚ as the triangle ΕΑΖ, which is the maximum triangle of those passing by the axis, is to the minimum triangle ΓΑΔ.

Problem 13

The second part of *On the Section of the cone* ends by the problem of proposition 57 (Heiberg; 268-272) in which he proves that the biggest of the given triangles has the biggest perimeter and conversely. For this demonstration Serenos uses a series of preceding lemmas (propositions 52-56).



The triangle ΑΓΔ is bigger than the triangle AEZ, thus the perimeter ΑΓΔ is bigger than the perimeter AEZ.

Third part of the treatise *On the Section of a Cone*: an extension of the Book XII of Euclid's *Elements*

The last group of propositions 58-69, constitutes a separate section of the treatise dealing with the volumes of right cones in relation to their heights, their bases and the areas of the triangular sections passing through the axis. With these propositions, he enriches propositions already established by Euclid in his book XII of the *Elements*. The third group of propositions is completely separated from the preceding propositions. In this section Serenos gives always couples of propositions and in every couple he proves a property and its opposite.

If r is the ray of the base, h is the height, B the base, T the surface of the axial triangle and V the volume of the cone. We know the existence of the formulas which connect the radius, the height, and volume, the circle of the base and the axial triangle of an oblique cone:

$$V=\pi r^2 h/3, \quad B=\pi r^2, \quad T=rh.$$

If we use the notations r', h', B', T' and V' for the same elements of a second cone, propositions of this part of the treatise of *the Section of the cone* take the following form (Loria; 733-734):

- Propositions 58-59 (Heiberg; 272-276): If V=V', we will have T/T' = r' / r and conversely.
- Propositions 60-61 (Heiberg; 278-282): If B/B' = V^2 / V'^2, we will have T=T' and conversely.
- Propositions 62-63 (Heiberg; 282-286): If h=h ', we will have V/V' = T^2 / T'^2, and conversely.
- Propositions 64-65 (Heiberg; 286-290): If V/V' = h' /h, we will have T=T' and conversely.
- Propositions 66-67 (Heiberg; 290-296): If V/V' = B' /B, we will have T/T' = r'^3 / r^3 and conversely.
- Propositions 68-69 (Heiberg; 296-302): If V/V' =B^2 / B'^2, we will have T/T' =r^3 / r'^3 and conversely.

Book V of *The Conics*

This book deals with normals to conics regarded as maximum and minimum straight lines drawn from particular points to the curve. In this book Apollonios has put a series of propositions which lead to the determination of the evolute of each of the three conics. This book is much more original than the preceding ones. He considers various points and classes of points with reference to the maximum and minimum straight lines which it is possible to draw from them to the conics i.e. as the feet of normals to the curve (Heath; 159).

In lieu of Conclusion

In propositions 16 and 24 of the treatise *On the Section of a Cone* Serenos is searching the maximum and minimum sides (prop. 16) and triangle (prop. 24). For the other sides or triangles, he writes that "the most approaching (line) or the most approaching triangle of the maximum is bigger than the most distant". This expression evokes the following expressions used by Apollonios. In proposition 6 of the Book V of *The Conics* (Rashed;238) Apollonios uses the following formulation: "... As for the other straight lines, those of them that are closer to the minimal straight line are less than those that are farther from it". This shows that perhaps there was a tradition of mathematicians working on the problem of maximum and minimum for rectilinear figures in both traditions. Apollonios was working on the problem of maximum and minimum for 3rd order equations and Serenos was working on the problem of maximum and minimum on 2nd order equations as Euclid shows us in the Books II and VI of *The Elements.*

We can find the same formulation in the enunciation of propositions 7-10, 12, 34, 35, 64-67, 70 of the book V of *The Conics*, "while among the other lines, this which is closer of this minima line will be smaller than the one which will be farther". In proposition 16 of the same book he writes "If a point is taken on the minor of two axes of an ellipse such that the segment of the minor axis between it and the vertex of the section is equal to the half of the latus rectum, then of the straight lines drawn from the point to the section the greatest is the part of the minor axis which is equal to the half of the latus rectum, and the smallest is the complement of the minor axis and of the other straight lines [so drawn] those of them drawn closer to the maximal straight line are longer than those drawn farther, ..."

With this formulation he develops the enunciation which corresponds to the lines of propositions 16, 17, 19-21, 73-77 under the form: "this which is more closer of the minima line will be greater than the one which is farther".

Finally in proposition 72 (Rashed;460) Apollonios writes that: "If a point is taken below the axis of a parabola or a hyperbola, and it is possible to draw from it two straight lines such that the part which the axis cuts off from each of them is one of minimal straight lines, then the closer of those two straight lines to the vertex of the section is greater than all [other] straight lines drawn from that point to the arc of the section from the vertex of the section to the other, second, straight line, and of the remaining straight lines drawn to that arc on both sides those drawn closer to it are greater than those drawn farther, and second straight line is smaller than all straight lines drawn from the point to the remaining [part] on that side of the section, that is the complement of the first arc on that side, and of the remaining straight lines drawn to that other [complementary] arc those drawn closer to it are smaller than those drawn farther". Propositions 18 and 72 use the two forms on the lines approaching the maxima and minima lines.

We can mark the relations between the formulations of the enunciation of propositions 16 and 24 of the *On Section of a Cone* and those of propositions 6-10, 12, 16-21, 34, 35, 64-67, 70, 72-77 of the book V of *The Conics*. We can not say that Serenos Knew the Book V of *The Conics* but we can see the existence of similar expressions – enunciations between these two treatises.

ASTRONOMY IN LATE BYZANTINE ERA: A DEBATE BETWEEN DIFFERENT TRADITIONS

Gianna KATSIAMPOURA
National Hellenic Research Foundation, GREECE
katsiampoura@yahoo.gr; katsiampoura@eie.gr

Abstract

In the Late Byzantine era (late 13^th^-15^th^ c.), specially in Constantinople, the capital city of the Byzantine Empire, we could find few scholars, who wrote about astronomy following the Ptolemaic tradition. Conversation about this mathematical science was very popular between scholars, and the main subject was renovation of astronomical data. In the same period, in Mongolian Persia, near the Byzantine Trebizond, there were healthy observatories at Maraga and Tabriz, where scholars followed the Islamic tradition, and in Provence the Jewish common of Caraites created a new astronomical school, which was based in Hebrew rules.

Soon, the basic principles of Persian and Jewish traditions were transferred in Constantinople. In these conditions, three teams were created about astronomy: first, the scholars who followed the Ptolemaic astronomy and believed that the solution of the problems was the right study of ancient Greek corpus, second, the scholars who imported principles of Persian astronomical texts, and, third, the scholars who accorded with the principles of Caraites.

In this paper we will present, first, the transmission of ideas, second, the three schools with their representatives, and, third, the debate between them. Then, we will try to interpret the main arguments in this conflict and the ideology behind them, and at least, the effects of this fruitful conversation.

Introduction: Astronomy in the Palaeologan Era

In the second half of the 13th century, after the restoration of the Byzantine Empire in Constantinople, in the era that was commonly called "Palaeologan Renaissance", a special interest in science and especially astronomy appears in the small Empire, particularly by a group of scholars in the Imperial Court. This interest is particularly evident, judging from the works that are saved and by the debate and the discussion they caused. It is therefore interesting to see from the one hand the results of this interest on the scientific level, and on the other hand the motivations, the various influences, the debate and its outcome, and how they fit in the socio-cultural and political context of its time and influence it accordingly.

Traditionally, the interest of the Byzantines in astronomy, from Late Antiquity, is focused in finding the positions of celestial bodies, predicting eclipses and making calendar calculations. The basis of Byzantine astronomy was the works of Ptolemaic astronomy, namely the Almagest (*Μαθηματική Σύνταξις*) and Handy Tables (*Πρόχειροι Κανόνες*), as well as the work of commentators, especially the work of Theon of Alexandria, Small Commentary on Ptolemy's Handy Tables (*Θέωνος Αλεξανδρέως Υπόμνημα είς τούς Προχείρους Πτολεμαίου κανόνας*). The important difference in this last period of

Byzantium is both the increase of the number of astronomical works and the introduction of different astronomical traditions from East and West.

This fact is closely related to the real need to renew the Ptolemaic work, but also in opening the now small Empire in a cultural level. Byzantine scholars appear to be the recipients of scientific ideas that come from the Persia of the Mongols, and from the West, Italy and the Jewish communities of Provence. The official public relations and marketing communications with both the Empire of the Mongols in the late 13th century and the West, in an effort to unite the churches, seem to have played an important role in this phenomenon. Byzantium at this stage appears as the crossroads between the ancient Greek tradition and foreign influences. It therefore creates a cycle in the context of imperial power with slots for the renewal of the existing and attraction of the new scientific ideas, which are processed efficiently, with consequences that will not appear until much later, in the scientific domain as well as in the internal ideological conflicts that divide the empire.

Traditions and persons

From the late 13th century, Byzantine scholars are interested in mathematical astronomy, and this is particularly evident from the manuscripts that are saved and from the discussion that they have caused. It is typical to organize public debates among scholars,[1] a first form of Academies, which will be developed later in the West, focusing on astronomy. On this basis, three main schools of astronomy were formulated: the Ptolemaic, the Persian and the Western. It is interesting to see the progress, their development but also the persons who played an important role in the formation of traditions.

The Ptolemaic tradition

The founder of the Ptolemaic tradition is Theodore Metochites, a senior official at the court of Andronicus II Palaeologus. Metochites had studied the work of Claudius Ptolemy, and of other astronomers, mentioned in his works: Theon, Apollonius of Perga, Serinus, etc. The practice of astronomy had been very productive: he wrote an *Introduction to the Almagest* (*Προεισαγωγή είς τήν τού Πτολεμαίου Σύνταξιν*)[2] and *Astronomike Stoicheiosis*[3] (*Elements on the astronomical science*, *Στοιχείωσις έπὶ τή αστρονομική έπιστήμη*). His aim was a work that would combine the astronomical theory of Ptolemy, as shown in *Almagest*, with practical applications, as stated in the *Handy Tables* and in the Theon's *Commentaries*. The aim of Metochites is to make accessible to a wider audience through his work, a science difficult and demanding as astronomy is.

What is new in the case of Metochites is the perception of nature and its link with the overall policy stance. According to Metochites, the main concern of people is to be aware of the natural world. The natural world is subject to constant change (flow, ροή), and understanding requires knowledge of ancient Greek science and observation through the senses.[4] It is important therefore to investigate by observation and mathematical knowledge of the universe, to interpret the apparent disarray in order to prove the laws that determine the changes and to see the final order (in the tradition of saving the appearances). So man will be driven to ground peace through knowledge, observation and senses.[5] In this context, the special interest of Metochites for predicting eclipses and the encounter with contemporary theocratic-Hesychast views which prevailed at the clergy is explained. The orientation of Metochites then is secular, with major importance in the ancient Greek knowledge.

Metochites' interest in astronomy spread "like wildfire",[6] according to his contemporaries, in Constantinople, then finding work in a continuing series. One of the most important of them was Nikephoros Gregoras, also a high official in the imperial Court, who, after studying on the Ptolemaic works, submitted a proposal to reform the calendar to emperor Andronicus II. This proposal was ultimately not accepted for reasons of political and social equilibrium, but eventually was imposed nearly two centuries later, in 1578, by Pope Gregory XIII. In the same tradition participate Nicholas Kavasilas, Isaac Argyros, etc.

The Persian tradition

The persian-islamic was the second astronomical tradition which developed in Constantinople after the 13th century. From the 13th century, the Empire of Mongols had developed the study of astronomy, with emphasis on observation, as

shown by the two observatories that were established in Maragha and Tabriz. At this time, through trade and diplomatic relations with the Mongols, and the Empire of Trebizond, which functioned as an intermediary station, the Byzantines were in contact with the works of astronomers who followed the Persian school.

Gregory Chioniadis was the rapporteur of this trend. Chioniadis visited Tabriz and studied close to Shams al-Din al-Bukhara and translated into Greek a series of Arabic and Persian texts. The translations are of the *Zij as-Sanjari* (al-Khazimi, c. 1120), the *Zij al-Ala'I* (al-Fahhad, c. 1150), and the instructions of the Persian astronomer Shams Bukhari. These translations came into the hands of a monk in Trebizond, named Manouel.[7]

George Chrysokokkes,[8] a Byzantine astronomer, physician and geographer, studied astronomy with Manouel in Trebizond and around 1347 wrote one of the most important and most well-known astronomical works of the 14th century, titled *Introduction to the Syntaxis of the Persians (Είσαγωγή είς τήν Σύνταξιν τών Περσών)*.[9] This work became extremely popular in the Byzantine Empire, mainly in Constantinople, as well as in the West, while it continued to be reproduced for a long time after the Ottoman occupation (in the Greek world, in particular, it was still being reproduced during the 19th century). Its numerous copies, dozens of which have survived in manuscript form, are a strong evidence of its popularity. George Chrysokokkes actually introduced Persian astronomy to the 14th century Byzantine Empire and the West. It was a period when Byzantium bitterly criticised the work of Ptolemy, which seemed to fall short of astronomical calculations, as we said before. As a result, the circumstances were suitable for turning to other astronomical traditions and methods of calculation. The work consists of the prologue, 51 chapters and the astronomical tables. The astronomical tables of the Introduction are based on *Zij-I Ilkhani*, the work of Nassir al-Din Al-Tousi.[10] The pattern of the content is as follows: the introduction recites the headings of the following chapters, according to the pattern of scientific works of Late Antiquity. The first chapters are dedicated to calendar questions, while the subsequent chapters study the motion of the Sun, the Moon and of the five known planets (Saturn, Mars, Venus, Jupiter, Mercury). Some chapters are dedicated to the eclipses of the Sun and the Moon, a subject that concerned particularly those who studied astronomy in the 14th century. The last part includes chapters dealing with astrological matters, such as drawing astrological charts and finding the horoscope. The way the position of celestial bodies is calculated facilitates both the drawing of astrological charts and calendar calculations, such as finding the exact date of Easter. *Introduction* includes some methodological mistakes resulting in considerable variances in calculations. Based on the tables of Al-Tousi and without having the relavant text, Chrysokokkes made some mistakes. For example, he mistakenly supposed that the first meridian (72º east) passed by a non-existent city he called Τυβήνη, while he implemented Ptolemaic and Persian formulas at the same time, etc.

In the next years the *Introduction* was followed by a series of books on Persian astronomy, directly influenced by the particular work. One of them was the third volume of the *Three Books on Astronomy (Αστρονομική Τρίβιβλος)*[11] by Theodore Meliteniotes, which was released as an independent text titled *Tradition in the Persian Rough Tables (Παράδοσις είς τούς Πρόχειρους Κανόνας)* and was attributed to Chrysokokkes until recently. Another work directly connected with the *Introduction*, which seems to simplify its tables, was found in Cyprus and must have been written shortly after Chrysokokkes' work.[12]

Theodore Meliteniotes, though following Ptolemy, knew and introduced elements of the Persian astronomy for the sake of comparison. Meliteniotes in his work aims to compare the very long Ptolemaic tradition with the more recent Persian one. He used the same examples in both books so that the differences could be more easily understood. His work had three chapters. In the first book, the writer presents those elements of arithmetic considered necessary for astronomy students, while in the second book he presents the basic elements of the Ptolemaic system. The third book is focused on Persian astronomy. Meliteniotes in this part of the work follows Chrysokokkes and makes the same mistakes, although he attempts

to improve the Ptolemaic tables in order to make them seem more accurate.[13] The work aimed to introduce the science of astronomy to the readers and offer them all they needed to continue studying this science.

The Western tradition

The third tradition was influenced by the Karaites Jews, included scholars like Michael Chrysokokkis and Dimitrios Chrysoloras.

One of the main tasks of this tradition is Michael Chrysokokkis' *Book of six wings* (*Εκδοσις γεγονυία είς τό Ιουδαϊκόν Εξαπτέρυγον κατα τό 6943 έτος από τής αρχής τού παντός or Ιουδαϊκόν Εξαπτέρυγον*). The work was written in 1435 and had a considerable spread in the Byzantine and post-Byzantine period. At least 15 manuscripts and reviews survived and also supplement the rules, like those of Damascenos Studite (? - 1577).[14]

This is the Greek version of *Kanfe nesharim* of Immanuel ben Jacob Bonfils from Taraskon. Bonfils belonged to the Jewish community in the Languedoc-Provence, which flourished intellectually in the 13th and 14th century. The *Kanfe nesharim* (*The wings of eagles*, refers to the Exodus) became known as the *Sepher shesh kanafayim* (*Book of six wings*), because the astronomical tables are divided into six groups or wings (refers to Isaiah 6:2).

The book was written around 1365,[15] was translated into Latin in 1406 by Johannes Lucae e Camerino and used by Pico delle Mirandola. It has been also translated into Russian.

A key element of the spiritual connection of Provence in 1365 and Byzantium in 1435 is the history of Karaites. The "textual" Karaites Jews because of their philosophy that denied the oral tradition, and the writings made it evident, were translators to and from various languages: Hebrew, Latin, Arabic, Greek. The Karaitism spread in Europe since the second half of the 11th century by the Byzantines and Spanish students of Abu al-Faraj Furkan, who translated Arabic and Greek texts. Over the following centuries, the Karaites were a sufficient nexus between the various Jewish communities around the Mediterranean. Chances are that Michael Chysokokkis, acquired through the Jewish Karaites circuit prototype.

The main concern of *Book of six wings* was the calculation of eclipses.[16] The calculation of eclipses, as we saw, was one of the chief concerns of the Byzantine astronomers of the 14th and 15th century, and this explains the interest of both Chrysokokki to translate and transfer rules, and subsequent users.

The debate

The introduction of different traditions in Byzantine culture caused a series of controversies. Although the need to revise the Ptolemaic project was mutually acceptable, the proposals put forward differed. Metochites in his two works aimed to clean astronomy contaminants from Eastern, Persian and Islamic influences, which had come through translations. As he writes in *Stoicheiosis,* everything coming from the Persians, the Indians and the Scythians should be avoided, because the Byzantines, as Greeks, had sufficient supply.[17] He believed that only the study of the ancient could provide a solution to the problems that had become apparent. In this context, he claimed continuity with the ancient Greeks and of course, defended the emancipation of philosophy from theology.

On the other hand, the introduction of elements of Islamic tradition had to face a general Byzantine distrust toward anything Muslim. Gregory Chioniadis, as example, because it remained too long in Persia, was forced to draw up a Confession of Faith.[18] Another facet of the great interest in astronomy is the conflicts that broke out between scholars themselves. The most famous of these is the conflict between Nikephoros Choumnos and Theodore Metochites[19] and that between Barlaam of Calabria and Nikephoros Gregoras[20] in response to the prediction of eclipses. The important thing here

is that the debate about astronomy covers a range of other causes, especially political strife and struggle for power in the imperial Court. In this case the money by means of scientific knowledge and power in the exercise.

Some first conclusions

From the above, it is clearly outlined a society that goes beyond the strict limits imposed by cultural Christianity and open to different cultures. Byzantium seems to be the crossroads of different cultural traditions, which brings its own cultural capital and creates a new tradition. This creates an identity that includes both the Greek scientific tradition, and others, without religion to no longer be the main feature. This tradition through the manuscript and diplomatic relations will be exported mainly to the 15th century in the West and there will affect the cultural processes.

On the other hand, at this stage, Byzantium, claiming its ancient heritage, led to a secularization, which would conflict with hesychasm. The image of an open and changing universe and man who can know by observation and predict natural phenomena contributed to this perception. The intensity of the relationship between scholars and secular authority in the church-religion will be seen later in the attitude towards the union of churches, which is discussed in the Council of Ferrara-Florence.

Another interest point is also the attitude and the social position of intellectuals. Byzantine scholars appear to be involved with –and to influence– the power, and knowledge seems to be an instrument of social and political recognition.

Abstract

In 1563 it was published in Goa the first modern book about the Asian natural world. Its author, Garcia de Orta (c.1500-1568), was a Portuguese physician who had lived in Asia for more than thirty years. The Colóquios dos simples *contains an accurate description of some of the most important Oriental plants, drugs and spices. The information published by Orta was not only the result of his erudite readings and medical practices, but also of the experience of several field actors.*

In fact, Orta was at the centre of a complex network of political elites, administrative officers, apothecaries, merchants, adventurers and other credible informants. These men were particularly able to answer to specific inquiries about the Asian natural resources. Even if their written reports had a limited circulation, they were available to Orta. Some of these informants were clearly referred by Orta in his Colloquies; *others were only recently identified.*

In this talk, I intend to follow the invisible tracks of some of the informants of Garcia de Orta. These virtual travels will show the different roles played by each field actor in the emerging of a new botanical knowledge about the Asian Portuguese Empire.

[2] PhD Student of History and Philosophy of Sciences.

Introductory notes

Colóquios dos simples was the first modern book on plants, spices and fruits from Asia edited by an European. It was published in Goa, in 1563. The text was written by Garcia de Orta, a Portuguese doctor who lived in India from 1534 to 1568. Each chapter of the book describes a virtual conversation between Orta and his interlocutor, a Spanish physician named Ruano. In the first colloquy, Orta presents to his readers his intellectual project. Recently arrived to Goa, the curious Ruano begins the dialogues saying to Orta:

> "I came with a great desire to know about the medicinal drugs (such as are called the drugs of pharmacy in Portugal) and other medicines of this country, as well as fruit and spices. I further wish to learn their names in different languages, and the trees and the herbs which they are taken."[3]

Through the fifty-eight chapters, Orta attempts to reformulate the knowledge about the Asiatic natural world. Aware of the diversity of the printed, manuscript and oral information that circulated in ports, markets and hospitals, both in Europe and in Asia, the physician wants to re-establish coherence to this knowledge.

Starting off from the texts, Orta travels through testimonies which he has reinforced with experience. A new order is thus established through a wide-ranging and patient work of collecting and validating the news he valued as legitimate from each source.

In this article I want to illustrate Orta's *modus operandi* in his appropriation of novelties from the India's natural world. In order to establish himself as an authority, Garcia da Orta uses both his own experience and the testimony of people in whom he trusted.

Texts

Garcia de Orta appears to know profoundly a vast bibliography of medicine and botany[4]. He reveals to the reader his wide medical practice, which in 30 years of living in India has made him well acquainted with the uses of drugs unknown in Europe. If his trust in *bezoars*, *herbs of Malabar*, *teriacas, pau-de-cobra, pau-de-Malaca* or *raiz–da-China* demonstrates his openness to what is new[5], it is also remarkable his ease in the therapeutic application of some products from the West Indies, such as the guaiaco which he already took with him in 1534 when he set off to Goa[6].

The belief in these new products, unknown to the Latin, Greek and Arab authors, opened to Orta the perspective of becoming the new Authority from those faraway places. Nevertheless, if Orta's project did not fulfil the requisites of credibility demanded by such an epistemological change, his work would have resulted in a major failure. Therefore, Orta's methodology had to obey rules that were implicit to the minds of the community of wise men from which he came, and by which he wanted to be recognized.

That is why Orta never dispensed with the texts. Texts were, as often as possible, the departure point for each intervention. It was this knowledge, fixed in words, that Orta wanted to challenge. But Orta did not base himself solely on books. Besides a vast library, the physician had an important collection of precious stones and bezoars, as well as samples of seed, gums, resins, fruits and woods, which he exhibited to his curious visitors. In the same way, he kept an orchard which trees and vegetables which provided him with flavoursome fruits and with the materials for his therapeutic experiments[7].

Orta only stands for what he has ensured that is true[8]. The novelty that he describes results, first and foremost, from his experience. The drugs which Orta saw or experimented were the ones he described more assuredly[9].

Orta –who produced the drugs of the King[10], who served in the courts of Cambay and of Deccan, who had close contact with rulers, religious men and civil servants posted to the Orient, who practiced medicine in a hospital in Goa, who

debated knowledge with apothecaries and physicians, who talked with merchants, travellers and *men worthy of faith*– validated a wide diversity of knowledge.

The merchant routes, the main ports of supply, the origin and destination of the drugs, prices, weights or measurements were information to which Orta attributed as great a value as to the names of the drugs, the description of the plants, their qualities or ways of application.

News that Pliny, Dioscorides or Avicenna had gathered and, since the arrival of the Portuguese to the East, were complemented and sometimes put in question, by reports like those of Duarte Barbosa or Tomé Pires, whose manuscripts had a wide circulation.

These Portuguese travellers were pragmatic observers. They witnessed, to a Europe *deprived* of novelties, an empiric approach to the Asian natural world. And yet, myth continued to be a part of the language they used. The possibility of the existence of the wonders of Pliny, Polo, Conti, Mandeville or Varthema remained in those lands that these men could not reach.

Orta tried to denounce some of their excesses, maintaining nevertheless the possibility of survival of some of the myths. His amazement, faced with the unexplained behaviour of the *árvore-triste*, of the *erva-mimosa* or of the tamarind leaves, lead him to simply register the mysterious, without searching for a justification.

On the other hand, the myth around the magical properties of the unicorn horn or of the *coco-das-maldivas* leaded him to caution. He promised in these instances to keep his readers informed on the progress of investigations. We find the same prudent approach on the disclosure of therapeutic virtues of some bezoars or of the hedgehog stone.

Context

The practices of a whole group are then gathered in *Colóquios dos Simples*. In his text Garcia da Orta includes reports of merchants, physicians, apothecaries, sovereigns or administrative officers. As I will show bellow, the type of information that each professional gives to the doctor depends on his own practical competence. In order to validate each testimony, Garcia da Orta associates the content of the news to the technical ability of his informants. He does not ask a merchant for his medical views, as he does not interrogate a lapidary on horses' prices.

The credibility of Orta's speech depends therefore on his judgement in analysing the news that are brought to him, as well as on the way in which he describes his own experience. He aims at confronting the past at every opportunity. His knowledge emerges not from a whim, nor from odd observations, not even from a simple pragmatic interest, but from a dialogue with Antiquity.

The Courts at Cambay and Deccan

Orta divulges in his work the information collected at the Courts of these exceptional interlocutors. He relates the veracity of the information to the high standard of their provenance.

At the Court at Cambay, Orta associates the strategic importance of the alliance established between the Sovereign and the Portuguese elites with the trust in the information brought by his Persian, Turkish and Arab doctors. The news about the *raiz-da-China*, secretly entrusted to him by a nobleman[11]; on the effects of the bangue, which Orta collected from Bahadur's secretary, or the confidences from the Sultan to Martim Afonso de Sousa[12], all this gathers greater relevance for being associated to the elites of Cambay. The success of the assault of the Capitan-General Martim Afonso de Sousa to Diu –an important achievement of the Portuguese political and commercial strategy– seems to go beyond the tactical value of the Portuguese presence at that fortress. The relationship that was established between the two politicians or between the Portuguese elites and the local courtiers manifested its richness also in the construction of a new knowledge.

The same mechanism was used to divulge the news collected at the court of the Deccan. Nizamoxa, the powerful and wise king, is introduced to us as our doctor's personal friend. The friendship between the two men is presented as an opportunity to reveal confidences.

[10] Garcia de Orta, *Colloquies*, 152.

[11] Garcia de Orta, *Colloquies,* 379.

[12] Garcia de Orta, *Colloquies,* 55.

But even if it seems that Orta might have cured Nizamoxa several times, who rewarded him with much wealth and amazing offers[13], he still could not manage to get the sovereign to entrust him with the secret composition of *teriaca*[14]. The physician insistently questioned the king on the list of components of that magical medicine, and yet never managed to get more than an evasive reply.

Informants

Administrative officers and merchants

Information gathered from administrative officers seems to equally dispense with proof. Coje Percolim[15], Jorge Gonçalves[16], Diogo Pereira[17], António Pessoa, António Galvão, Simão Alvares or Bastião Lobato are characters whose technical expertise or professional abilities seem sufficient to validate the information which they provide to Orta. The reliability of the novelty is therefore ensured by the credibility of these agents. The fact that this empirical information was shared with Orta by the King's officers reveals that the physician was close to the Portuguese elites in Goa and attests to the fact that Orta was part of the decision-making circles. In a two-way relationship, these men bring him information, expecting from Orta the validation of their knowledge as well as the eventual establishment of commercial networks.

But Orta also trusts merchants. He solicits information about the origins and prices of the drugs they trade. Perhaps as evidence of their friendship and appreciation, some offer him valuable gifts[18], others confide him with their secrets[19]. We thus learn how to falsify camphor or how to discern true from fake gems. Still others confirm to Orta the whereabouts of cities they know, like Babylon[20] or Bukhara[21]. And yet not all of them manage to inspire the physician's trust. In fact he alerts his readers to the lies told by lapidaries[22], as well as to the lack of scruples of the merchants in Diu's bazaar[23]. The sharing of secrets is a transitional mechanism often used by Orta. Rather than keeping to himself these secrets, liable to be of interest to many, he shares them with his audiences. By teaching the reader to be able to distinguish fake from true, Orta gains the trust of those he addresses.

Apothecaries and doctors

Doctors and apothecaries were also privileged informants. The doctors of Cairo, Aleppo and Damascus with whom Orta has relationships provide him with reliable information resulting from their own experiences[24]. The Arabs instruct him on the synonymy in the various regional languages. The Gentile doctors explain Orta the efficacy of some of the local folk medicines[25].

The apothecaries take a prominent place in the *Colóquios dos Simples*; because they made the drugs of Cambay, they had profound knowledge of their trade and were particularly trustworthy. In two separate chapters they are presented as close interlocutors to the Governors[26]. Politicians seem to have greater trust on the pragmatism of these men on the ground and on their good sense in the relationship with local chiefs, rather than on the knowledge of academics. Nevertheless, Orta demonstrates that the knowledge of the apothecaries does not surpass his own.

25 Garcia de Orta, *Colloquies*, 218, 223.

26 Garcia de Orta, *Colloquies*, 108, 374.

'People worthy of faith'

Finally, 'people worthy of faith': this anonymous mass that Orta trusts, brings him samples, information and news from the regions through which they travel. It is through them that the doctor complements his information on the benjuy[27], cloves[28], camphor[29], *coco-das-maldivas*[30]*, cubebas*[31]*, avacari*[32]*, coru, lacre*[33], incense[34] or the metallic aloe.

None of these men and women, pragmatic people and keen observers, bothers with the past of these drugs. Their knowledge focuses on the present and projects itself onto the future. They have little or no interest in comparing the sample with the text or with the drawing, and even less in understanding the intrinsic value that each plant has within the local culture. Taken out of their mystical context, each plant, stone and animal has merely the value of a drug or a panacea. To these pragmatic informants, only the empirical knowledge, the practical use, the price or the strategic potential are of interest.

Orta's credibility

Orta evokes multiple artefacts to affirm himself as an authority. The care he takes in the selection of credible informants and in the divulgation of plausible news makes his text believable.

The arrival of correspondence during the conversations between Orta and his interlocutor and the close vigilance paid to the comings and goings of ships at Goa's harbour reveal a physician who is deeply attentive and informed about all the news which arrive from the four corners of the World to the capital of the Portuguese Overseas Empire.

The doctor also needs to present himself as a witness of facts. Orta demonstrates his insertion in the Portuguese context. The military campaigns in which he accompanied Martim Afonso de Sousa allow him to visit the *Elefanta* Temple[35]; the news which he collected about the second siege of Diu, or the statements he makes about the betrayal of Magalhães, all these give credibility to Orta before a Portugues audience. The reliability of his account, and the exactitude of his historic discourse, legitimate the novelty of all that Orta saw, heard, experienced and enquired about the Asian natural world. His importance in the complex and fragile game of political interests is also made clear by the trust that he gained with the rulers of Deccan, Cambay and Cochin.

The news which Orta wants to validate is therefore supported by its clear insertion in the world of the Portuguese political elites… but not only in Goa, since the physician makes a clear reference to the property in Bombay which was given to him by the King[36].

To assert his own authority, Garcia de Orta aptly manages both scientific knowledge and personal relationships.

The relationship which Orta establishes with his readers presupposes complicity. By sharing in *Colóquios dos Simples* his secrets, Orta makes the reader his accomplice.

More that cyanide or hemlock, Orta feared the "*idle people and the sharp tongues"*[37]. The physician hopes to obtain recognition of his authority through the sharing of his knowledge with his readers.

Final notes

During three decades of living in Asia, Garcia de Orta established invisible links that attached him to each of his informants. Written to legitimize his authority as a physician, *Colóquios dos Simples* is Garcia de Orta's greatest tribute to all those who, through those first decades of Portuguese presence in Asia, travelled through the lands of the Orient, enquiring,

taking samples, taking risks, aiming to build a new body of knowledge about Asia's natural world. A utilitarian and empirical view which completes and corrects the truths for a long time established in text. In 1563, *Colóquios do Simples* relinquishes to Europe a plural knowledge, resulting from a new way of approaching reality.

THE GERMAN AND EUROPEAN NETWORK OF THE PROFESSORS OF MATHEMATICS AT HELMSTEDT IN THE SIXTEENTH CENTURY[1]

Pietro Daniel OMODEO
Max-Plank-Institut für Wissenschaftsgeschichte – Berlin, GERMANY
pidaom@gmx.net

Abstract

This paper addresses the 16th century international scientific network of the professors of mathematics appointed at the University of Helmstedt. It presents part of the results of a research project accomplished at the Herzog August Library of Wolfenbüttel (Germany) in 2010.
The Protestant University of Helmstedt had two chairs of mathematics as was prescribed by Melanchthon's University Reform. Since its foundation (1576), it was strictly connected to Wittenberg and other Protestant universities. Most of its 16th century professors of mathematics came from the University of Rostock. They were supported by Heinrich Brucaeus, a Flemish Professor of mathematics and medicine who had studied in Gent and Bologna, taught in Rome, and worked as a physician in Belgium and Portugal and, apart from that, was well acquainted, among others, with the Danish astronomer Brahe. Brucaus helped his countryman Cornelius Martini to become part of the Philosophical Faculty of the University of Helmstedt and introduced Magnus Pegel (Professor of lower mathematics 1575-81), Franciscus Parcovius (lower mathematics 1586-90), and the Scotsman Duncan Liddel (lower mathematics 1591-93, superior mathematics 1593-1600). Other academics were: Erhard Hofmann (Professor of superior mathematics 1576-93), who came from the University of Jena, and Simon Menz (Professor of inferior mathematics 1593-1606), a Melanchthonian humanist from Wittenberg. Remarkably, the latter was involved, together with the Scott Magister John Johnston, in a cosmological dispute against theses of the Italian philosopher Giordano Bruno, who participated in the cultural life of Helmstedt University around 1588-1590.
The biographies and works of the Helmstedt mathematicians show a late-Renaissance scientific network over a North-European area (German Lutheran Universities-Breslau-Denmark-Flanders-Scotland). I would also like to highlight the importance of this network for the circulation of scientific theories (especially in connection with post-Copernican astronomy).

[1] This research was accomplished in Wolfenbüttel and Berlin with the support of fellowships from the *Herzog August Library* and the *Max Planck Institute for the History of Science Berlin* in 2010.

The University of Helmstedt was founded in 1576 as the *Academia Iulia Helmstediensis* by Duke Julius of Braunschweig (1528-1589) in order to consolidate the Reformation which he had introduced into his realm. In fact, Julius considered the university to be a powerful means to forge a new class of Lutheran theologians and administrators. One of the principal authors of its statutes was the learned theologian David Chyträus (1531-1600), a professor at Rostock who endorsed Philipp Melanchthon's cultural program and thus organized the new university following the models of Wittenberg and Rostock. In particular, the curriculum was inspired by the so-called 'German late humanism,' or *deutscher Späthumanismus*.[2]

The University flourished especially after Duke Heinrich Julius (1564-1613) succeeded his father in 1589. Thanks to his patronage and his renown as a learned man, he attracted to Helmstedt some leading exponents of the humanist culture, science and philosophy of the time: the man of letters Johannes Caselius (1533-1613) in 1590, the mathematician Duncan Liddel in 1591 and the logician Cornelius Martini (1568-1621) in 1591. Moreover, the Renaissance philosopher Giordano Bruno resided in Helmstedt as a member of the university and a protégé of the Dukes from January 1589 until April 1590. It should be noted that these people were foreigners or of foreign origins: as Caselius's family came from the Netherlands, Liddel came from Aberdeen, Martini from Antwerp, and Bruno from Nola by Naples. Duke Heinrich Julius himself was open to foreign cultural influences: among other things, he established at his court in Wolfenbüttel a company of English actors,[3] he personally visited the Danish astronomer Tycho Brahe at his observatory-castle on the island of Hven,[4] and resided at the magnificent court of Emperor Rudolph II in Prague from 1607 until his death in 1613, when Kepler was imperial mathematician there.[5]

Following Melanchton's *ordo studiorum*,[6] the University of Helmstedt attached great importance to mathematics. Two chairs of the philosophical faculty were devoted to the teaching of mathematics, at least at the beginning. They were divided into a lower (or elementary) class and a higher. The following table sums up all available information on the lectures during the half century after the opening of the University:[7]

Semester[8]	**Lower mathematics**	**Higher mathematics**
1581 A	(Prof. Pegel) -Geometrica ex Euclide -Astronomica ex Cornelio Valerio	(Prof. Hofmann) -Arithmetica Frisii -Theoriae planetarum -Doctrina triangulorum
1582 A	vacant	-Elementa geometriae Euclideae -Precepta arithmetices Gemmae Frisii -Doctrina secundorum mobilium eorundemque usum in Tabulis Prutenicis
1587 B	(Prof. Parcovius) -Arithmetica vulgaris Gemmae Frisii -Cosmographia Honteri	-Secundorum mobilium theoria -Doctrina triangulorum planorum et sphaericorum -Praecepta arithmeticae cossicae
1594 B	(Prof. Menz) -Geometriae tractatus -Arithmetici libelli -Ratio conscribendi calendaria anniversaria de syderum motibus atque congressibus -Doctrina sphaerica e libello Ioannis de Sacrobusto	(Prof. Liddel) -Geometriae fundamenta figurarum usum et geodesiam una cum triangulorum doctrina -Theoriae coelestium motuum iuxta triplicem hypothesin una cum tabularum tum Alphonsinarum quam Prutenicarum explicatione

7 Here and in the following information about lectures is derived from: http://uni-helmstedt.hab.de (7 Nov. 2010).

8 The capital letter A indicates the summer semester and B the winter semester.

Semester[8]	Lower mathematics	Higher mathematics
1595 B	-Sphaericae doctrinae elementa -Anniversaria calendaria -Arithmetica Gemmae Frisius	-Theoriae coelestium motuum iuxta triplicem hypothesin, una cum tabulis Alphonsinis et Prutenicis -Quadripartitum Ptolomei -Tabulae Directionum
1597 A	-De primo motu doctrina sphaerica -Rationes geometrice investigandi insignorum urbium, insularum et regionum intercapedines ex tabulis sinuum rectorum sive semichordarum -Arithmetica Gemmae Frisii	-Secundum et tertius liber Pomponii Melae una cum historia et descriptione regionum secundum recentiores -Quadripartitum Ptolemei et Tabulae Directionum.
1599 A	-Doctrina Sphaerica -Tractatus de Iudiciis ecclipsium et cometarum -Arithmetica practica	-Doctrina sinuum et triangulorum -Theoriae planetarum, secundum hypothesin Ptolomaei et Copernici, et illam Mundani systematis hypothesin, quam describit Tycho Brahe, lib. 2 De aethereis phaenomenis -praecepta calculi Alphonsini, et Prutenici, ac praeterea supputatione apparentiarum coelestium in singuliis theoriis, ex observationibus Ptolemaei et Copernici, per doctrinam triangulorum
1600 B	-Tractatus quadripartitus -Quaestiones sphaericae Hartmanni Beieri -Doctrina de calendariis anniversariis conscribendis et prognosticis astrologicis subinde attexendis	vacant
1602 B	-Elementa mathematicis -Arithmetices practices (Gemma Frisius) -Sphaera a Iohanne de Sacrobusto conscripta	(Prof. Schaper) -Doctrina secundorum mobilium, iuxta hypotheses Copernici et Alphonsinorum
1603 B	-De Sphaera libellum -De tempestatibus praecognoscendis regulas astrologicas -Arithmetica practica -Computus ecclesiasticus Iohannis de Sacrobusto	-Geographica -Priores Euclidi libri
1604 B	-Arithmetica -Sphaericum libellum D. Casparis Peuceri de circulis coelestibus et primo motu	-Euclidis -Pomponius Mela de situ orbis
1613 B	vacant	-Doctrina planetarum iuxta Alfonsinos et Copernicum
1620 A		-Doctrina Sphaerica seu motus coeli primi
1623 A		-Regulae arithmeticae practicae vulgares -Doctrina primi mobilis
1625 A		-Doctrina primi mobilis seu sphaerica

From this overview, however incomplete it is due to the lack of documents relative to many semesters, it is possible to trace some relevant features of the *curriculum studiorum* at Helmstedt. Programs show a certain continuity over the years: Euclidean geometry, spherical astronomy and arithmetic in the introductory class, and trigonometry, planetary theory and astronomical computation in the higher. It should be remarked that geography also was part of the regular curriculum of mathematics. Some professors (Mencius and Liddel) taught astrology and calendar computation. Hofmann offered lectures on algebra. Beginning in 1594, thanks to Professor Liddel, Copernicus's planetary hypotheses were presented to students along with the traditional Ptolemaic system (and, in the case of Liddel, also the geo-heliocentic system of Tycho Brahe).

From 1576 to 1629, six professors taught mathematics: Magnus Pegel, Erhard Hofmann, Franz Parcovius, Duncan Liddel, Simon Menz and Heinrich Schaper. Here an overview follows:

Year	Chair of lower mathematics	Chair of superior mathematics
1575	1. Magnus Pegelius	
1576		2. Erhardus Hofmannus up to his death (1593)
1581	Pegel abandons Helmstedt	
1582	Hofmann holds both chairs?	
1586	3. (3 October) Franciscus Parcovius	[John Johnston's astronomical disputations]
1590	Parcovius moves to the Faculty of Medicine	[Giordano Bruno at Helmstedt, January 1589-April 1590]
1591	4. (24 July 1591) Duncan Liddel	
1593	5. Simon Mencius, already professor of Latin (dies in 1606)	Duncan Liddel up to 1600
1601		6. Heinrich Schaper
1606	vacant (Schaper both chairs?)	
1629		(October) Schaper's death

As a matter of fact, all professors who occupied a chair of mathematics in the sixteenth century had received their education at a Lutheran university: Jena, Wittenberg, Frankfurt on Oder and Rostock, or Helmstedt itself. This already conveys the sense that Helmstedt belongs to a network of universities sharing a confessional background. In this framework, Rostock had a special importance. Pegel, Parcovius and Liddel, but also other eminent professors of the philosophical faculty like Caselius and Martini, came from there. In particular, the three mathematicians were tied with the Rostock professor Heinrich Brucaeus, himself a Flame, and, following in his footsteps, they chose a further career as physicians.

Scholar	Education
Magnus Pegel	Rostock
Erhard Hofmann	Jena
Franz Parcovius	Rostock
Duncan Liddel	Frankfurt (Oder), Breslau, Rostock
Simon Menz	Wittenberg
Heinrich Schaper	Helmstedt

The 'Rostock professors' of the philosophical faculty shared a humanist background and an inclination toward Melanchthon's teaching, or 'Philippismus.' Menz had studied in Wittenberg under the guidance of the *praeceptor Germaniae*. It is therefore not surprising that he chose, for his classes on astronomy, a textbook of Melanchthon's son-in-law Peucer. Another noteworthy aspect of the University of Helmstedt is the presence of many foreigners in the philosophical faculty. Liddel and Martini were born beyond the borders of the Empire, Caselius had Dutch origins, and their friend and supporter Brucaeus was Flemish. To the list of foreign scholars one could also add Bruno. Furthermore, it is remarkable that several Scotsmen seem to have studied, at least for a period, at Helmstedt: for instance Master John Johnston who, around 1586, defended the Aristotelian cosmology in two above-mentioned disputations, and, a few years later, the alchemist Duncan

Burnet of Aberdeen who took his degree in medicine under Parcovius in 1608.[9] Additionally, Caselius hosted Duncan Liddel in his house and, as we read in a letter of his, a nephew of John Craig.[10]

Apart from the classics from antiquity and the Middle Ages, also the choice of the textbooks for the teaching of mathematics clearly indicates a north-European cultural horizon. The following table sums the textbooks mentioned in the syllabi:

Author, *Textbook*	**Semester**
Euclid, *Elements*	1581A, 1582A, 1603B, 1604B
Gemma Frisius, *Practical Arithmetic*	1581A, 1582A, 1587B, 1595B, 1597A, 1599A, 1602B, 1603B
Sacrobosco, *Sphere*	1594B, 1602B
Sacrobosco, *Computus ecclesiasticus*	1603B
Ptolemy, *Quadripartitum*	1595B, 1597A, 1600B,
Pomponius Mela, *Chorography*	1597A, 1604B
Alfonsine Tables	1594B, 1595B, 1599A, 1602B, 1613B
Reinhold, *Prussian tables*	1582A, 1594B, 1595B, 1599A, 1602B?, 1613B?
Regiomontanus, *Tabulae directionum*	1595B, 1597A
Valerius, *Physica*	1581A
Brahe, *De mundi aetherei recentioribus phaenomenis*	1599A
Copernicus, *De revolutionibus?*	1599A?
Peucer, *De circulibus coelestibus et motu primo*	1604B
Beyer, *Quaestiones in libellum de sphaera*	1600B
Honter, *Rudimenta cosmographica*	1587 B

Helmstedt professors lectured on several standard works: Euclid's *Elements* for geometry, Sacrobosco's *Sphere* for spherical astronomy, Ptolemy's *Tetrabiblos* for astrology and Pomponius Mela's *Chorography* for geography. It shall be however stressed that Melanchthon encouraged the employ of such classics, as emerges in particular from his introductions to Sacrobosco and *Tetrabiblos*. Exercises of astronomical computation relied upon the *Alfonsine Tables* as well as the 'Copernican' *Prussian Tables* (*Prutenicae tabulae*) of the Wittenberg professor Erasmus Reinhold (1511-1553). Among sixteenth century textbooks, the *Arithmetic* of the Flemish mathematician, geographer and instrument maker Reiner Gemma Frisius, professor at Louvain, was used uninterruptedly. The textbook of astronomy employed in the summer class of 1581 refers to a work of the Louvain professor of the Trilingual College Cornelius Valerius (1512-1578), perhaps his *Physica seu natura philosophiae institutio* (Antwerp, 1572) which contains a traditional description of the cosmos, celestial spheres, elements and meteorological phenomena. Apart from Reinhold's *Prussian Tables*, other works stemming from the Wittenberg academic milieu are the commentary on Sacrobosco, *Quaestiones in libellum de sphaera Ioannis de Sacrobusto*, of the theologian and mathematician Hartmann Beyer (1516-1577) and the *Elementa doctrinae de circulis coelestibus et primo motu* of the Wittenberg theologian and professor of mathematics Kaspar Peucer (1525-1602). The book on geography for the winter semester 1587 is plausibly the *Rudimenta cosmographica* of the fervent Lutheran Johannes Honter of Transylvania. Professor Liddel's lectures are apparently the most ambitious, as he lectured on advanced scientific books: Tycho Brahe's *De mundi aetherei recentioribus phaenomenis* (Uraniborg, 1588) for planetary theory and Johannes

[9] D. Burnet, Propositiones... de virginum cachexia pro licentia sumendi doctoris medicinae (Helmstedt 1608).

[10] J. Caselius, epistle to J. Craig (Helmstedt, 1 Maz 1607), in D. Liddel, *Ars medica* (Hamburg 1608), f. †8*r*.

Regiomontanus's *Tabulae directionum* for trigonometry. It is also plausible that he used Copernicus's *De revolutionibus orbium coelestium*, of which he owned two copies, to introduce the heliocentric hypothesis, as announced in the syllabi. Even relative to geography, he sought to integrate classical and modern sources, as he lectured on Pomponius Mela as well as on "histories and descriptions of lands according to the most recent [explorers/scholars]" (*historia et descriptione regionum secundum recentiores*). One can assume that he employed a book like Simon Grynaeus's *Novus orbis*, a collection of reports on western as well as oriental countries.

In a study on the international network of the University of Helmstedt from its origin until its closing in 1810, Rolf Volkmannm stressed its early connection to northern-European protestant countries.[11] As this scholar showed, in the first years many students as well as the professor of physics Nicolaus Andreas Granius (ca.1569-1631) came from Lutheran Sweden. Several professors where Protestants from Flanders, in particular Antwerp (the physician Johann Böckel, Cornelius Martini, the theologian Johannes Fuchte) or had studied abroad, in particular at Louvain (the jurist Virgilius Pingitzer) and Basel (the jurists Johann Borcholten, Johann Jagemann, Andreas Cludius and others) - as an exception to this northern-European horizon, one can mention the fact that Caselius had studied also at the Italian universities of Bologna and Pisa. In the seventeenth century Helmstedt developed close contacts with the University of Leiden in the Netherlands.

It shall be remarked that the religious element influenced not only the teaching of theology, but also the international network of the mathematicians. This fact clearly emerges from the biographies of the above mentioned professors. I would like to show this on the basis of two of them: Magnus Pegel and Duncan Liddel.

* * *

Magnus Pegel (1547-ca.1618?) was born in Rostock and studied in his hometown where he graduated in 1569. He was appointed at the University of Rostock as a professor beginning in 1572. Thanks to the support of his father-in-law David Chyträus and, perhaps, of Brucaeus, he was appointed at Helmstedt as a professor of mathematics already in 1575, that is, a year before its opening. In 1581, he was dismissed for his dissipated behaviour (possibly alcohol abuse). Duke Julius wanted to keep him in Wolfenbüttel as a court mathematician, perhaps to benefit from his technical competencies, but Pegel preferred to return to Rostock. There, he took a degree in medicine and maybe worked for a while as a physician. In 1591, he became a professor of mathematics at Rostock and taught there until 1605 when he was dismissed. He fled to Prague where he stayed at the court of Rudolph II until the Emperor's death in 1612. From his writings, we know that he was familiar with the Landgraves Wilhelm IV and Moritz of Hessen-Kassel, who were generous patrons of astronomy, and their instrument builder Jost Bürgi.[12] Pegel reported also that he visited Brahe whom he admired for his astronomical instruments and data recording but not for his geo-heliocentric cosmology which he, in fact, rejected.[13] He also sojourned at some point in Florence where he accomplished some stellar observations in order to compare the latitude of the Italian town with that of Rostock and measure the Earth's radius.[14]

Pegel publications are very rare: *Universi seu mundi diatyposis* (Rostock, 1586) and *Aphorismi thesium selectarum de corporibus mundi totius primariis* (Rostock, 1605), both of which tackle astronomy and natural philosophy, *Thesaurus rerum selectarum* (Rostock, 1604), which presents medical and technical inventions as well as considerations on jurisprudence, and a discourse on language and printing.[15] These publications reveal an extraordinary technical fantasy and very original natural views. Among the inventions presented in the *Thesaurus*, a work dedicated to the Emperor Rudolph II, some are quite ambitious and surprising, for instance the project of a submarine (*navigium submarinum sive subaquaeum singulare*), the feasibility of which is however quite difficult to believe. His most innovative philosophical and cosmological theses are: the cosmos is a finite sphere included in infinite space; the material spheres deputed, according to traditional cosmology, to transport planets, do not exist; the sky is homogenous, and constituted of air; all celestial bodies (stars, planets and comets) are made out of the same elements; stars and planets are alive; astronomy would do better without mathematical hypotheses because physical explanations should be preferred to mathematical ones. Moreover, Pegel supported the Capellan planetary system, according to which the inferior planets, Mercury and Venus, encircle the Sun. He also reassessed the possibility of physical vacuum, surprisingly identifying it with absolute space (*locus sine corpore*) and a vitalistic principle.[16] All of these theses are revealing of a radically anti-Aristotelian world view. Additionally, the requirement of an astronomy *sine hypotheses* can be traced back to the French philosopher Pierre de la Ramée (1515-1572), who

* * *

Duncan Liddel (1561-1613) was a mathematician and physician. Much information about his life can be derived from a letter (Helmstedt, May 1607) of Caselius to the Scottish mathematician and court physician to King James VI of Scotland and I of England. Liddel left Scotland to study in Europe. He sailed to Danzig and reached Frankfurt on Oder, at which University he matriculated. He attended the classes of Craig, who was at that time professor there. Liddel stayed then in Breslau, where he entered the humanist and scientific circle of the Italo-Hungarian man of letters Andreas Dudith-Sbardellati (1533-1589) and the physician von Krafftheim (1519-1585). There, he studied mathematics under Paul Wittich (ca.1546-1586), one of the most highly thought of German mathematicians of the time, who strongly influenced Brahe on his way to the invention of the geo-heliocentric planetary model.[18] Liddel then returned to Frankfurt on Oder (1582-1583) to study medicine and teach mathematics and philosophy. He subsequently headed to Rostock (beginning in 1585), at which University he was warmly welcomed by Heinrich Brucaeus, and met Caselius, who would later invite him to Helmstedt. In this period, Liddel visited Brahe on Hven (in 1587) and became familiar with the research projects accomplished at the latter's observatory. Caselius reports that Liddel taught Copernicus's planetary hypotheses along with the Ptolemaic and the Tychonic already in Rostock, and that it was the first time that such doctrines were taught together at a German university.[19] This information about Liddel's lectures of astronomy is confirmed by a letter of a student of his, Daniel Cremer, who attended the courses of mathematics in 1588 and 1589 (*Docuit Duncanus Liddelius Scotus in Academia Rostochiana Mathemata, quando ego auditor fui anno 88 et sequenti*): in his classes, the professor taught planetary theory (or the doctrine of 'second motions') according to Ptolemy (the 'followers of Alfonso X of Castille' are explicitly indicated), Copernicus and the 'third new' hypothesis, that is, geo-helicentrism (*prima [hypothesis] Alphonsinorum, secunda Copernici, et alia tertia nova*).[20]

Liddel came to Helmstedt on Caselius's advice. In a letter of recommendation to the Academic Senate preserved in the *Niedersächsisches Staatsarchiv Wolfenbüttel*, Caselius (on 1 January 1591) emphasized Liddel's mathematical expertise and stressed his close connection to Brucaeus and the acquaintance with Brahe.[21] At Helmstedt, according to Caselius's report and the extant *ordines lectionum*, Liddel continued to teach the three concurring hypotheses on the planetary system. He stayed in Helmstedt until 1607, when he returned to Aberdeen with his mathematical books, among which were two copies of *De revolutionibus* and a rare handwritten copy of Copernicus's *Commentariolus*.[22] He endowed the local University with a fund for the support of poor scholars in 1612 and the Marischal College with a chair of mathematics in 1613.

Liddel was very diligent in publishing his medical writings, for instance a collection of his numerous medical disputations, *Disputationes medicinales* (Helmstedt 1605), and an *Ars medica* (Hamburg 1607). By contrast, his mathematical writings are very rare. Still, two disputations by him are preserved in Wolfenbüttel: *Propositiones astronomicae de dierum et annorum differentiis et caussis* (Helmstedt 1591), and *De philosophia eiusque instrumentis* (Helmstedt 1592).[23] The latter was defended by Cornelius Martini, professor-to-be at Helmstedt, and a close friend of Liddel. The disputation *De philosophia* is revealing of Liddel's philosophical conception of mathematics, which he regarded as one of the three speculative disciplines together with metaphysics and physics. The corollaries (*coronides*) to the theses are a refutation of Ramism. In particular, the fourth corollary rejects de la Ramée's requirement of an astronomy 'without hypotheses,' a program which, by contrast, had been embraced by Pegel. Liddel was also the author of a lost introduction to mathematics, titled *Parerga mathematica* (Helmstedt, 1595), mentioned by Brahe in a letter to Liddel's pupil Cramer in which the Danish

astronomer protested, with quite rude expressions, that Liddel did not acknowledge his authorship of geo-heliocentrism.[24] Concerning Liddel's opinion on cosmology, very little can be said: he was probably a crypto-Copernican. To his classes he presented the heliocentric hypothesis from a mathematical point of view, that is, with no open commitment relative to its physical reality, as shown by the fact that he taught the Copernican system along with the concurring models of Ptolemy and Brahe. Nonetheless, from Cramer we know that he was inclined to accept heliocentrism also from a physical point of view and objected the physical tenability of Brahe's model.[25]

Connections: Aberdeen, Frankfurt on Oder, Breslau (Dudith, Crato, Wittich), Rostock (Brucaeus), Denmark (Brahe), Hamburg (printing of the Ars medica), Edinburgh and London (Craig).

* * *

To sum up, the teaching of mathematics played an important role in the first years of the University of Helmstedt. Brilliant scholars, well inserted in the actual scientific debate, were attracted to the newly-founded institution. The originality of their achievements is witnessed by the conceptions of Pegel, the ambitious lectures of Liddel and the writings of Bruno. A significant aspect is the cosmological interest witnessed by Pegel, Bruno and Liddel who contributed, in a way or another, to the post-Copernican debate. Relative to the connections of the Helmstedt mathematicians, they are revealing of an essentially northern-European network; it includes Lutheran universities (Rostock, Wittenberg, Frankfurt on Oder, Jena), important centres of astronomical research (Hven, Kassel, Prague), as well as Flanders/Netherlands, England and Scotland. I would define it as a northern-European Protestant network. The confessional element seems to have played an indirect role in the international contacts of the professors of mathematics, because the political and theological context determined their concrete possibilities of collaboration and scientific exchange. No significant connections with Catholic countries can be detected, apart from the fact that several Flemish scholars escaped from their country precisely for religious reasons and took refuge in Rostock and Helmstedt. Bruno was a kind of comet in the history of the University of Helmstedt, yet he could have influenced the atmosphere of tolerance and openness toward scientific novelties characteristic of the philosophical faculty and, in the seventeenth century, also of the theological.

VOYAGES ALONG MERIDIAN LINES IN EUROPE

Suzanne DÉBARBAT
SYRTE – Observatoire de Paris,
Centre National de la Recherce Scientifique (CNRS) et
Université Pierre et Marie Curie, FRANCE
Suzanne.Debarbat@obspm.fr

Abstract

After the creation of the Paris Observatory meridian line, in 1667, Picard made measurements along it from Amiens to La Ferté-Alais. After his death (1682), Cassini enlarged it in 1683 up to Bourges, later (1700-01), with Cassini II, up to the Pyrenees. The end came only in 1718 from the northern to the southern borders. After measurements in Lapland (1736-37), a new campaign is performed in France by Lacaille around 1740. This may explain why this peculiar meridian was chosen in 1791 to give birth to "une mesure révolutionnaire: le metre", whose definitive length was fixed, after new measurements (1792-98), in 1799. Other voyages along a meridian line occurred in Europe (1800-20) in Lapland, Spain, Great Britain and in Central Europe (1816-55) with the longest meridian arc ever measured. Despite these new measurements, the length of the "metre" has never been changed, leading 50 years ago to adopt its modern realization for the "Système international d'unités", the SI, in 1960.

Scientific travels in Europe, in the present days, are frequent but our predecessors were very numerous as well, according to the conditions of their time; Copernicus, Halley and others could be mentioned and, for France, Picard in Denmark and along the French coasts with La Hire, Delisle in Russia and Siberia, Cassini II in England, Cassini III in Austria and many others.

Among scientific voyages in Europe, the paper concentrates on those whose purposes, being mostly organised at national or European level, were made to get a better knowledge of the shape of planet Earth. They concern, more or less, from West to East, Great Britain, France, the Low Countries, Spain, Central Europe, Sweden and Finland. Their influence over science is consequently considered.

First travel for France along a meridian arc

Influenced by Frisius (1508-1555) and Snellius (1580-1626) with a method named *triangulation*, Picard (1620-1682) launched, in France, the idea to measure a meridian arc, in view of the improvement of the map of France, requested by Colbert, minister of Louis XIV, around 1663. After the creation of the *Académie Royale des Sciences* in 1666, followed a few months later, in 1667, by the foundation of the *Observatoire Royal,* Picard and one of his colleagues, academician Auzout

(1622-1691), built a portable quadrant (1667) equipped with refractors, themselves having a filar micrometer they had built in 1666.

A portable quadrant, a second pendulum clock recently (around 1655) made by Huygens (1629-1695) in the Low Countries and a zenith sector, which later would influence Bradley (1693-1762), third Royal Astronomer of the Royal Observatory in Greenwich, was Picard's equipment to perform the measurement of a meridian arc. It was more or less centred in latitude on the Paris Observatory the symmetry axis of which represents the reference meridian line. For measuring the base (about 11km) of his triangulation (about 111km), Picard used pieces of wood about 4 meters long, all data being here given in the Decimal Metric System, not in use at that time.

Picard worked on this triangulation during several short trips he made between 1669 and 1670. The instruments were carefully carried in horse or donkey carriages but, for his long (3.25m) zenith sector, for latitude determinations from the two extremities of triangulation, they were moved by men in a special carriage. One can easily think of the difficulties encountered in such a geodetic operation. After its end Picard published (1671) his *Mesure de la Terre*, which represents, for France, the creation of geodesy.

It is said that the result of Picard's length for one degree (57 060 toises of 1.95m), made known to Newton (1643-1727) in 1684, provided him a confirmation for his famous law of gravitation. What is sure is that in Newton's *Principia* (1687) many numerical data are given provided by French scientists of the time, mostly astronomers.

First travels along a complete meridian arc for France

After Picard's death, in 1682, Cassini I (1620-1712) took care of the project Picard had proposed (1681) to the French *Académie Royale des Sciences*. The project, related to the shape of the Earth, was bearing the idea Richer (1630-1696) had, having to reduce the length of the second pendulum when in Cayenne (1672), concerning the sphericity of our planet.

Cassini I began the prolongation of the meridian arc, from Picard's Southern point to Bourges, a town situated in the centre of France; but Colbert's death stopped the operation. It could only be pursued by himself and his son Jacques, in 1700 and 1701, leading them to the Pyrenees, the limit between France and Spain. The Northern part could be measured only on the occasion of Louis XIV's Flemish war. The achievement occurred in 1718 and the corresponding publication came in 1720 by Cassini II (1677-1756), his father being dead. The end of the measurements led, as well as those made with his father, to a prolate Earth, contrary to Newton's law.

The controversy between partisans of Newton and the two Cassinis, had as consequences, under the leadership of the French *Académie Royale des Sciences*, two expeditions as close as possible to both the equator and the pole of the Earth.

Meanwhile, in France, Lacaille (1713-1762) and Cassini III (1714-1784) had re-measured the *Méridienne de France* in 1739-1740, having new and better-made instruments. The results were published under the title *La Méridienne de l'Observatoire Royal de Paris, vérifiée dans toute l'étendue du Royaume* […] in 1744, confirming the oblate shape of the Earth. The complete and scientifically established map of France could be achieved, covering the country with an incredible set of triangles, including four along meridian lines to make linkages more secure, in combination with some parallels.

Cassini IV (1748-1845), who had only helped his father before his death in 1784, had to achieve and to present the map to the *Assemblée constituante* in 1790 after the *Révolution Française* (1789), which leads him to abandon his position of the now named *Observatoire de la République* in 1793.

During all the 18th century in France, there is no special mention of great improvement for travelling with scientific instruments despite makers' efforts to improve carriage of various types. But what is insured is that instruments makers had been able to build more accurate instruments: metallurgy had improved to the point of having more flat limbs whose graduation was more regularly obtained; parts of them were made with better quality optical glass; clocks had been improved after the Harrison's (1693-1776) success with his mariner clocks, but were not yet available at affordable prices for current uses. Some improvements occurred in instruments, but mostly for determinations at sea. Improvements for terrestrial measurements would arrive by the end of the century.

Travel along a meridian arc in Lapland

The *Expédition de Laponie*, as it is named in France, was placed under the leadership of Maupertuis (1698-1759), but it included other French members of the *Académie Royale des Sciences* and also, a Swedish, Celsius (1701-1744), to become famous for the degree of his temperature scale.

Maupertuis, who had been in England in 1728, came back convinced about Newton's theory, perhaps also influenced by Voltaire (1694-1778), who had attended his grandiose burial ceremony the previous year. In 1735 an expedition had left France to measure a meridian arc in Equator, at that time named Peru, with Godin (1704-1760), La Condamine (1701-1744) and Bouguer (1698-1758), together with two Spanish officers to become famous: de Ulloa (1716-1795) and Juan y Santacilia (1713-1773).

For determining their position at sea, they had a newly built octant by Hadley (1682-1744). Maupertuis, who went to Lapland by boat, had a similar one, but also what was needed for geodetic and astronomical observations --his portable quadrant is in Berlin from the time he was a member of the Berlin Academy of Sciences, while the one employed by the Spanish is in Madrid. Both are improved versions of Picard's quadrant, for geodetic measurements, and of his sector, for latitude determinations. They also had, of course, clocks, ephemerides and it was decided to perform gravitational measurements with a pendulum. Following Celsius' suggestion, the base was measured (1736/37 winter) on the ice of the river, and the triangulation extended between Kittis in the North and Tornea in the South.

To have a clear impression of measurements, made only between 1736 and June 1737, the best is to read the book published by the Abbé Outhier (1694-1744) or, for young children, E. Badinter's book illustrated in colour by J. Duhême (Seuil Jeunesse, 2003). Among other things, Outhier had mentioned that mosquitoes were so numerous that when eating their bread slices, toasted with grease and despite some veil covering their heads, they were indeed eating mosquito toasts! Outhier also recalls the pleasure they had to sleep between sheets, after having had to sleep with their clothes and boots on, without being able to remove them for two weeks!!

The *toise* they employed is preserved, under the name *Toise du Nord*, in the collections of the Paris Observatory as well as the one brought by the *Expédition du Pérou* named *Toise du Pérou*. According to Maupertuis' calculations, compared with Picard values, the conclusion was favouring Newton.

Travel along a meridian arc for a metre

A new linkage between British and French meridians of reference for longitude was launched in 1784 by geodetic means. Ramsden (1735-1800) was working to built a new instrument, a theodolite of altazimuth type, while Borda (1733-1799) requested the help of the instrument maker Lenoir (1744-1832) for a new system: the repeating circle issued from Mayer's (1723-1762) full circle, known from mid-18th century. Both would be ready for the operation in 1787; it was successful, so that the repeating circle would be chosen for the determination of a new standard for length in view of the uniformisation of weights and measures in France, decided in 1790, more or less as a consequence of the French Revolution.

While latitude and longitude were being determined in Great Britain (1796-1798), the French were travelling once again along the *Méridienne de France* (1792-1798). Travel conditions are difficult due to the circumstances, including the *Terreur* and some war between France and Spain. Manuscripts from Delambre (1749-1822), Méchain (1744-1804) and their collaborators let us know about the difficulties encountered, the discussions, at European level of the time; a definitive length was given to the metre in 1799.

In Great Britain, the 1796-1798 operations were made from Dunnose (Isle of Wight) to Nettlebed, later to Clifton, in the North of the country, to the Tees' mouth, crossing Arbury Hill. While Delambre and Méchain's measurements confirm, like Lacaille and Cassini III, the diminution, from North to South, for lengths of meridian arcs covering one degree in latitude, Mudge (1762-1820) and his collaborators find the opposite. They had the new instrument by Ramsden, achieved by one of his collaborators. Other measurements are made in 1801, again in 1802 and, in 1803, the conclusions given by Mudge to the Royal Society confirm the diminution, contrary to Newton's law. The discrepancy, at Arbury Hill, of the order of five arcseconds in latitude has a great effect on the conclusions for the arc. Mudge recalls the anomaly found by Méchain (3.24") in Spain, close to Barcelona.

Travels along meridian arcs in Sweden, Great-Britain, Spain and Finland

The development of Newton's works in France by Clairault (1713-1765), D'Alembert (1717-1783), followed by Legendre (1752-1833), Lagrange (1736-1813) and Laplace (1749-1827) will bring new travels along meridian arcs, at the beginning of the 19th century. After his first works, Laplace had shown in 1793 that Newton's flatness (1/230) of the Earth was given different numerical values when issued from meridian arc measurement (1/250) compared with gravimetric methods (1/320). Later, after other studies by Legendre and Lagrange, it was seen that the Lapland meridian arc showed anomalies, while data from Peru were in agreement with the measurements in France. In using them, and not the Lapland one, Delambre had found 1/307,8.

New measurements were decided by the Royal Swedish Academy of Sciences, and Svanberg (1771-1851) was in charge for measuring an arc as close as possible of the preceding one. It was indeed a little bit longer; two bases were measured: Maupertuis' one, between Avasaxa in the North and Niemisby in the South; and a second one between Pullingi and Avasaxa. Apparently, Maupertuis' error had come from his astronomical measurements, not from the angles. After Svansberg's measurements, Newton was not discussed any more. But Mudge had still the anomaly.

In 1806, in Spain, Biot (1774-1862) and Arago (1786-1853) left France in view of pursuing the measurements along the French meridian from Dunkerque to Barcelona, to prolongate it up to the Balearic Islands. This new travel along this meridian line will allow the arc to extend, with a symmetrical length, on each side of latitude 45 degrees, for which the influence of the flatness of the Earth is almost negligible. The results are discussed in *Base du Systeme métrique décimal* (Vol. III), by Méchain and Delambre (1810); the last one examined several aspects for the length of the metre. The conclusion is that the difference between a possible «new metre» and the 1799 value is small, and that there is no need to change its value.

On the other hand, this campaign confirms Newton's results, but does not explain those found in Great Britain. After some new calculations, published by the Spanish Rodriguez (1776-1821) in 1813, several experiences were organised along meridian arcs in Great Britain. A repeating circle, used by Kater (1777-1835) in Arbury Hill, provides the same latitude value. Mudge came to Dunkerque with the Ramsden/Berge instrument, confirming Delambre's determination of latitude. It is too much, and something needs to be made, but 1812 is not a favourable year for Franco-British cooperation.

This occurrence will come in 1816, through the *Bureau des longitudes*, an institution created in 1795 more or less influenced by the British Board of Longitudes. Biot left France in May 1817 equipped with a repeating circle made by Fortin (1740-1817), most probably the one which is in the Paris Observatory Collections. He also has a pendulum he employed, with Arago, in the Balearic Islands. The whole campaign, in which Arago and Humboldt (1769-1859), the German scientist then in Paris, participated from November 1817, ended with their return to Paris in January 1818. The anomaly in the centre of Great Britain is confirmed. Thus, several people recalled the deviations of the vertical mentioned by Bouguer, one of the members of the Peru expedition, due to the mountains in Equator.

Travel along the longest European meridian arc measured by classical geodesy

This operation, in which were engaged people from Russia, Norway, Sweden,… along a meridian arc between the Baltic and the Black seas, is more or less a consequence of the discrepancies found between Maupertuis and Svanberg measurements. At the very beginning, Lindenau (1779-1854), director of the Seeberg Observatory, and W. Struve (1793-1864) were thinking about a meridian in the middle of Europe in longitude, which indeed was firstly an idea of J.-N. Delisle (1688-1768) after he had founded an observatory in Saint Petersburg, on the roof of the seat of the Russian Academy.

In 1737, thirteen years after his arrival in Russia, J.-N. Delisle had submitted the project of a meridian arc of 23°, aligned with the meridian of the newly installed observatory. To begin, Delisle measured a base, similarly to Maupertuis on the iced river in winter, between Doubky and Peterhoff. Delisle will not pursue the work, most probably because the expeditions to Lapland and to Peru had solved the problem raised concerning the shape of the Earth, favouring Newton.

The new meridian will have two more degrees than Delisle's project, 25 instead of 23. Similarly to Delambre and Méchain, measurements were made from a sea level to a sea level. The main actors of the subsequent voyages were a Russian general C. de Tenner (1783-1860), a Norvegian Ch. Hansteen (1784-1873), a Swedish N.H. Selander (1804-1870) and W. Struve, the founder of Pulkovo Observatory in 1839, Delisle's observatory having not been so much in use after his departure from Russia.

Seven arcs were measured, including 257 triangles, 10 bases, 13 latitude determinations along the meridian line of Dorpat (nowadays Tartu). This arc was, indeed, more or less in the middle of Europe in longitude as well as in latitude, a favourable position for a general geodetic map. With such length, the measurements along this meridian line, beginning in 1816 –after the end of the Napoleonic wars– ended in 1855. The publication was in two volumes (28 x 36 x 9 cm), plus an Atlas of 26 sheets for the drawings about the triangulation. The total length, measured by all these men and their collaborators, covers about 3000 km. They had all sorts of weather conditions, during the four decades they had to perform these various measurements.

With this European operation, it became clear that a general map of Europe was not far to be made. But a linkage between triangulations in the various countries was needed: Russia, Scandinavian countries, Poland, Prussia, Austria, France, Great Britain, … And even, W. Struve asked G. Everest (1790-1866) to check some linkage between Russia and India, in which geodetic measurements had been made from 1823 to 1843.

Toward the unification of weights and measures

During the second part of the 19th century, discrepancies began to appear, mostly after the measurements of the «longest meridian arc», in linkages between several parts of the triangulations.

As an example, clearly seen when linking Prussia to France, triangles could not be properly closed at the limit. After a very deep control, it was seen that this occurred because the metres employed for the Prussian operations were not exactly of the same length as the French reference, the *mètre des archives* defined as 3 *pieds* 11.296 *lignes* (1 ligne = 2.27

mm) of the *Toise du Pérou*. This *toise*, preserved in the collections of the Paris Observatory, was indeed the *Toise de l'Académie*.

The definitive *mètre* had been made by Lenoir, firstly in providing twelve pieces of iron and two in platinum prepared at the requested length, and measuring them accurately. They were, of course, not all of the same length. The reference taken for the *mètre*, the new French reference, was one of the irons ones, selected for being as close as possible of the mean obtained from the fourteen different lengths. On the other hand, despite the comparisons Angström (1814-1874) had made in Paris with his metre, more precise observations showed that its length was not exactly power minus ten of the French *mètre*.

Following all these remarks, it was decided –at the level of knowledge of the time– that it would be better to have an international reference. These considerations led to the creation in 1875/76 of the *Bureau international des poids et mesures* (BIPM), the International Bureau for Weigths and Measures. The reference for length would be the *Mètre des Archives*; for weight the reference would be the *kilogramme* under the form of a small cylinder which was, in 1799, deduced from the weight of one cube of water which sides were equal to one *décimètre*, a tenth of a *mètre*.

Among other consequences of all the measurements made in Europe through rather long voyages along meridian lines, was also the creation of the *Mittel-Europäische Gradmessung* (1861/62). As the name shows, it was a geodetic association related to Central Europe, but a few years later it became the *Europäische Gradmessung* (1864), the *Association géodésique internationale* (1866) and, after the inclusion of several other countries, the *Association internationale de géodésie* (1930). Very soon many other domains of cooperation would appear at the international level: solar watch, longitude determinations mostly after the discovery of wireless and its uses in astronomy and in geodesy.

All these developments, simultaneous to other scientific changes in different fields, both in science and in techniques during the 19th century, had several important consequences. To stay in the geodetic domain, the *Convention du Mètre* among seventeen countries was signed in 1875, leading to the adoption of the decimal metric system. To be noted, the most important character of this system of units is its decimal character, which became fifty years ago, in 1960, *Système international d'unités*, the SI, for International System of Units.

A few more comments at the end

At the time of Delambre and Méchain, and after addition of the meridian measurements in Great Britain, the length of the 1799 metre was recalculated; the differences were so small that it was decided not to change its length. Later, Biot and Arago examinated some anomalies in observations and found mistakes in their calculations. Again, it was decided not to modify its length. As noticed already by Lalande (1732-1807), the length of the meter, whatever its length was, is indeed a convention. Half a *toise* or the yard would have been as useful as all the measurements made, but such a decision was perhaps difficult in view of a new system not only for France but for the world.

As early as in 1799, Delambre had said that there was no need to modify the value of the length of the meter, many measurements having been made. It was also added that, in the future –after Delambre, Méchain, Arago, Biot, …-- nobody would do the same to verify this length.

This prediction has not been completely true, and the longest meridian arc was indeed measured by mid-19th century. But, as far as we know, it was not used to recalculate a length for the *mètre*. The only case known is most probably the subject of one of Jules Verne's books, whose title is *Aventures de trois Russes et de trois Anglais*. A meridian arc is measured in Africa, at a longitude appropriate to Russia in view of checking the length of the *mètre*. Let us say, when examining the part concerning the measurements, that almost word to word, the description comes from the volume about the Earth, one of the four volumes of Arago's book *Astronomie populaire*.

In Barcelona, to have an idea of the meridian arc, measured between Dunkerque and Barcelona, walk by the *Avinguda Meridiana*, up to the *Plaça de les Glòries Catalanes*. In a circular garden, there is a big piece of metal along one of its diameter. About its shape, it is said to represent, with some visibility, the central part of France, which caused some trouble to Delambre, similar to what Mudge had in Great Britain and Méchain in Catalonia, the scale, in altitude, was enlarged by a factor ten.

CONTRIBUTION OF JAPANESE PRINTED DRAWINGS OF AQUATIC ANIMALS BROUGHT TO EUROPE BY HOLLAND MERCHANTS IN THE 18TH AND 19TH CENTURIES FOR BIOLOGICAL DEVELOPMENT

Yuko TAKIGAWA
Kagawa University, JAPAN
sakanafriend@yahoo.co.jp; osakana@ag.kagawa-u.ac.jp

Abstract

During Japan's isolation from the west, Linnaeus established the scientific classification using binominal nomenclature, which was promptly accepted as a universal system by Western scientists. Therefore, concerning fish, except for some specimens and materials brought back to Europe by voyage naturalists, there were only a few Japanese ichthyological resources available in Europe. Those materials included drawings called "Poisson du Japan" associated with Isaac Titsingh, and a book titled Umi no sachi *(Boon of the seas), which were brought to Holland by the Dutch East India Company, the sole western trader with Japan. They are now stored in the Muséum National d'Histoire Naturelle, Paris.*

Umi no sachi *is a haiku anthology book of wood engravings in colour, published in 1762, Edo Period, Japan. It mainly contains illustrations of fish and marine invertebrates, in and around Japan, whose characteristics are described to some extent with accuracy. Admitting to the limitation of the illustrations, which often lack accuracy in the number of the fin rays or spines, European biologists in the early 19th century did however utilize the book as a reliable source material for their scientific works. Cuvier and Valenciennes often cited it as "the Japanese printed copy" in their work,* Histoire Naturelle des Poissons *(1828-1849). Moreover, in the plates for* Histoire naturelle générale et particulière des Céphalopodes Acétabulifères *(1834-1848), Férussac and d'Orbigny exactly copied and reproduced the drawings of squids and octopuses from the book.*

Based on my research on Umi no sachi in the Bibliothèque Centrale du Muséum National d'Histoire Naturelle, Paris, I would like to evaluate its academic value in the progress of science. The role of the book is also reviewed as media, which contributed to the biological classification in the 19th century by providing ideas and description of aquatic animals living in the unknown country.

During Japan's isolation from the west, Linnaeus established the scientific classification using binominal nomenclature, which was promptly accepted as a universal system by Western scientists. Therefore, concerning fish, except for some specimens and materials brought back to Europe by voyager naturalists, there were only a few Japanese ichthyological resources available in Europe. Figure 1 shows the international relations between Japan and Europe in the 18th and 19th centuries. During the Edo period, when Japan had an isolationist policy, Holland was the sole western trader with Japan. Materials concerning Japanese fish were brought to Holland by merchants or voyager naturalists who worked for the Dutch East India Company.

In this paper, I would like to evaluate the roles of those materials and their academic values, especially fish drawings brought to European countries by Holland merchants in the 18th and 19th centuries. Contemporary Japanese also showed keen interests in natural history, and thus, many natural history drawings including fish illustrations were made. I want to focus on their contribution to ichthyological work by French biologists, Cuvier and Valenciennes. Based on my investigations, I would also like to discuss the roles and significance of the drawings, not only from their contemporary perspective, but also for their academic value in today's scientific areas.

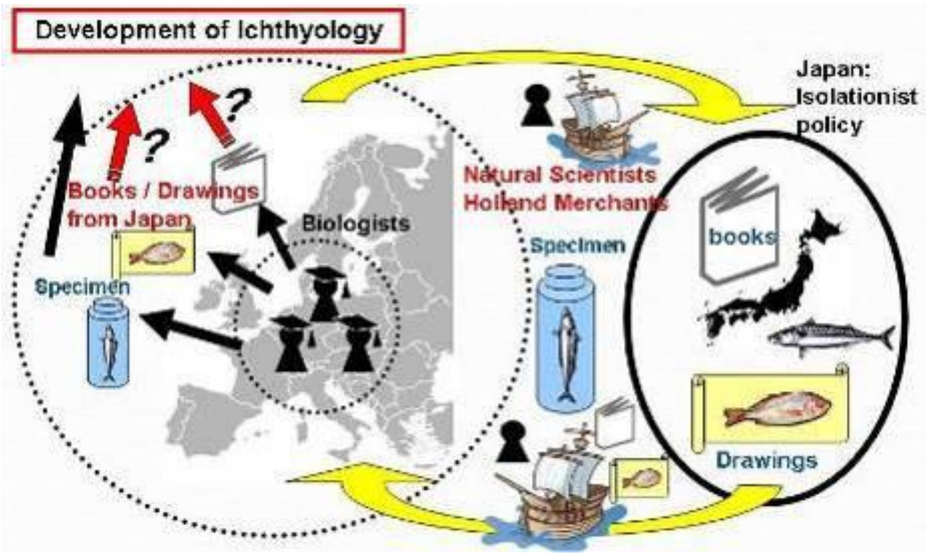

Fig. 1: Overview of this paper: the international relations and transfer of the academic source materials between Japan and Europe in the 18th and 19th centuries.

To understand the early period of ichthyology concerning Japanese fish, it is essential to analyze when fish in and around Japan were described and given their scientific names based on the Linnaean system of biological nomenclature. Historical background of this discipline gives us a good starting point, such as the western scientists who described the species, and the number of the new Japanese fish species they reported and described in their academic papers. As the ichthyological studies developed, the classification of species has changed accordingly. For example, species that once were regarded as different, now might belong to the same species. On the other hand, one species may have included different species. Both of the names of the scientists who described the species and the number of species which are still valid today are kindly given by the Japanese ichthyologist, Tetsuo Yoshino (University of the Ryukyus). Thunberg (1743-1828), who visited Japan from 1775 to 1776, was the Swedish physician who worked for the Dutch East India Company. Thunberg published 10 Japanese fish species, of which 6 species are still valid today. He sent his fish collection to J.C.M. Radermacher (1741-1783) in Batavia, who subsequently forwarded them to Houttuyn (1720-1798). Dealing with the Thunberg's Collection, Houttuyn was the first scientist who classified Japanese fishes and published reports on the 36 species of Japanese fishes in his work *Beschryving van eenige Japanese visschen, en andere zee-schepzelen* (Description of some Japanese fishes and other sea-creatures) in 1782 (Boeseman & Ligny, 2004: 71), in which 14 species are valid today. Temminck (1778-1858) and Schlegel (1804-1884) published *Fauna Japonica, Pisces* from 1842 to 1850, based on the enormous number of fish specimens collected by Phillipp Franz von Siebold (1796-1866). Siebold was the German physician who worked for the Dutch East India Company, who visited Japan from 1823 to 1829. Since Siebold collected both Japanese Fauna and Flora extensively, the number of the new fish species nominated by Temminck and Schlegel was, therefore, significant. However, ahead of Temminck and Schlegel, Cuvier (1769-1832) and Valenciennes (1794-1865) did publish as many as 32 Japanese fishes. This raises important issues of the French biologists Cuvier and Valenciennes. For example, how and why could they nominate Japanese fish species, and what were their source materials for the scientific descriptions.

Cuvier and Valenciennes were eminent biologists, who made great contribution to the development of ichthyology. From 1828 to 1850, they published their monumental work, *Histoire naturelle des poissons*, which consists of 22 volumes, 11,253 pages and 650 colour plates. *Histoire naturelle des poissons* contains 4,055 species, and among them, 2,311 were considered new species at that time (Bauchot et al., 1997: 27). Their work is still important and essential for ichthyologists today.

In the *Histoire Naturelle des Poissons*, Cuvier and Valenciennes clearly mentioned that two kinds of source information were available for them. One was fish specimens from Japan brought back by Langsdorff (1774-1852), who participated in the Russian Voyage under the command of Captain Krusenstern (1770-1846). To get a reply from Bakufu (Japan's feudal government), Russian missionaries had to stay in Nagasaki for half a year from 1804 to 1805. Although the Russian expedition failed to establish trade between Japan, those fish specimens, mainly from Nagasaki where the trading port with Dutch East India Company existed, were brought to Europe. Langsdorff donated 89 Japanese fish specimens to the Zoological Museum of Berlin (Paepke, 2001: 332), and they have been stored in the museum under the "Langsdorff Collection." The other source was Japanese books and drawings which had been brought to Paris from Japan.

The purpose of the present paper is to investigate the roles that these materials played for Cuvier and Valenciennes. For this reason, I would like to move on to details of these materials which are not biological.

The source materials which were used by Cuvier and Valenciennes consisted of three kinds of publications or drawings: first, *l'Encyclopédie japonaise* (in Japanese, *Wakan sansai zue*); second, "Poissons du Japon"; and third, Umi no sachi (Boon of the seas). The first two materials were brought back by Isaac Titsingh (1745-1812), who visited Japan three times from 1779 to 1784. As the chief officer of the Dutch East India Company, he stayed in Japan for about three years in total. Since he himself studied to be a physician and he was also interested in Japanese culture, he had scientific and cultural exchanges with many intellectuals throughout Japan. Those intellectuals included Rangakusha, some of whom were physicians and medical doctors who also studied foreign sciences. The Rangakusha had keen interests in natural history, and they collected many natural history materials, both specimens as well as well-drawn illustrations. Their collections also included natural history books, not only the domestics, but also foreign ones through Holland. Although the imported natural history books were very expensive, those intellectuals were eager to obtain them. Notables include: physicians Katsuragawa Hoshu (1751-1809) and Nakagawa Jun'an (1739-1786); Nagasaki interpreter, Yoshio Kogyu (1742-1800); and Feudal lords, Daimyos, Kutsuki Masatsuna (1750-1802) of Fukuchiyama, and Shimazu Shigehide (1745-1833) of Satsuma. Even after Titsingh left Japan, he kept in touch with those intellectuals by exchanging letters. Extensive research work by Frank Lequin has shown that the correspondences between Titsingh and his Japanese friends were extensive, including gifts, books and information. Thus, Titsingh became known as the Japanologist who was successful in possessing the first extensive Japanese Collection in Europe. In Paris, he deepened friendship with orientalists, Abel-Rémusat (1788-1832), who published Titsingh's works after he died.

Among the Titsingh's Collection in the French National Library (fig.2) is a set of illustrated Japanese encyclopedia called *Wakan sansai zue*, namely, *l'Encyclopédie japonaise*, consisting of 81 volumes, donated by Titsingh in 1803, which became the first Japanese printed books in the library (Lequin, 2003: 50). Cuvier and Valenciennes quoted the *l'Encyclopédie japonaise* in *Histoire Naturelle des Poissons*, with the aid of Abel-Rémusat, whose name is mentioned several times in the text to express their appreciation. The quality of the illustrations in the encyclopedia, however, is poor, so Cuvier and Valenciennes used it to grasp the characteristics and names of the fish.

The last remaining of the two materials is stored in the Bibliothèque Centrale du Muséum National d'Histoire Naturelle, Paris today (fig.2).

The second material referred to by Cuvier and Valenciennes was "Poissons du Japon," which is also associated with Isaac Titsingh. "Poissons du Japon" consists of 23 colour folios, which contains 47 drawings. The number of fish species amounts to 31, and the other species include Crustacea and a few turtles. Cuvier and Valenciennes highly valued the drawings in the "Poissons du Japon," and wrote as follows:

> The Duke of Rivoli possesses a superb manuscript, brought back from Japan by the late Titsingh, in which the Japanese names are added in European transliteration; … (Cuvier, 1995: 88)

As Cuvier and Valenciennes added to the text, the Duke of Rivoli was kind enough to show them the volume. It seems that they had not been able to use the "Poissons du Japon" as a referencial source, partly because it was in the private possession of the Duke of Rivoli. "Poissons du Japon" was referred to by Cuvier and Valenciennes only once in the *Histoire Naturelle des Poissons*, however, the quality of drawings impressed Cuvier and Valenciennes greatly enough to make them annotate it in the text. Through my investigation, it is getting clearer that the drawings of the "Poissons du Japon" were carefully copied and reproduced by hand, because there are almost the same drawings found in some libraries in Japan. The original drawings have not yet been found, but the handwritten notes attached to the existing drawings enable me to consider that the drawings were passed down among the famous physicians in Edo who had keen interests in natural history. Maybe one of them met Titsingh and offered to give him a copy.

Fig. 2: Photos of the Bibliothèque Nationale de France (left) and the Bibliothèque Centrale du Muséum National d'Histoire Naturelle, Paris (the right-most building).

The main source materials to describe Japanese fish for Cuvier and Valenciennes was the printed book titled *Umi no sachi*, which is a haiku anthology book of wood engravings in colour, published in 1762, Edo Period, Japan. It mainly contains illustrations of fish and marine invertebrates, in and around Japan, whose characteristics are described to some extent with accuracy. It was Katsuma Ryosui (1697-1773), a famous painter in Edo period, who drew the illustrations. Admitting to the limitation of the illustrations, which often lack accuracy in the number of the fin rays or spines, Cuvier and Valenciennes did however utilize the book as a reliable source material for their scientific works. The book is stored in the Bibliothèque Centrale du Muséum National d'Histoire Naturelle, Paris today. On the book, Cuvier wrote French names in the margins of the fish images by pencil.

Although the provenance of the book is uncertain, previous research has shown that it was stored as one of the items in the Stadtholder's Collection in The Hague. The Stadtholder's Collection was one of the most famous, so called "cabinet of curiosity," and many items such as paintings, prints, manuscripts, books, coins from all over the world were collected through the Dutch East India Company. Not only artefacts or human products, but also natural history collections, such as animal specimens were collected. After the French Revolution, the French Republican Army occupied Holland in 1795, and most parts of the Stadtholder's Collection were brought from The Hague to Paris by the French Army (Bauchot et al., 1996: 219). Together with other items in the collection, *Umi no sachi* was also taken and brought to Paris at that time, and has been stored in the Bibliothèque Centrale du Muséum National d'Histoire Naturelle, Paris since.

In the *Histoire Naturelle des Poissons*, Cuvier and Valenciennes referred to *Umi no sachi* as "l'imprimé japonais," "le recueil japonais," "l'ouvrage japonais," at least 39 times when they described the species. The number of the species they referred to in *Umi no sachi* amounts to 22 in total.

Here, the stonefish is shown as a case study. Cuvier and Valenciennes gave a new scientific name, *Pelor japonicum*, to this new species. It is possible to see Cuvier's handwriting by the stonefish drawing in *Umi no sachi*. He also mentioned its Japanese name, "Ogosse" in the text of the *Histoire Naturelle des Poissons*. Cuvier and Valenciennes described morphological characteristics of this species based on the examination of Japanese fish specimen brought back by Langsdorff in Berlin. Although the genus has been changed, the name of this species, *Inimicus japonicus* (Cuvier, 1829) is still valid today.

Interestingly enough, there is a case that Cuvier and Valenciennes described a new species based solely on the drawing in *Umi no sachi*, due to a lack of availability of the specimen of this species. Cuvier concluded that this drawing represents a special, different type of its neighboring species. Therefore, based on the characteristics of the drawing in *Umi no sachi*, Cuvier gave a new scientific name, *Cybium niphonium*, to this species. It is reasonable to consider that Cuvier named "niphonium" after this drawing from the Japanese book, because Japan can be called "niphon". The current scientific name of this species is *Scomberomorus niphonius* (Cuvier, 1832), therefore, although the genus has been changed, the specific name given by Cuvier is still valid. For this reason, this drawing in *Umi no sachi*, was actually used by Cuvier to describe the species when a specimen was not available.

It was not only Cuvier and Valenciennes who used the drawings in *Umi no sachi*. Here are the cases of Cephalopods, that is, the group of squids and octopuses. Monograph of Cephalopods, *Histoire naturelle générale et particulière des Céphalopodes Acétabuliferes* by Férussac and d'Orbigny, from 1834 to 1848, exactly copied drawings from

Umi no sachi. Two illustrations of squids (*Sepia*, Plate 9 and *Loligo*, Plate 18), as well as those of octopuses (Octopus, Plate 9), were copied from *Umi no sachi*.

Férussac and d'Orbigny monographs were usually drawn based on specimens as precise as possible. Seeing these figures, specimens from Far East countries were not available to them. This leads to me to conclude that Férussac and d'Orbigny did use *Umi no sachi* and exactly copied and reproduced the drawings. This proves that the Japanese drawings held enough academic value to be used to complete the monographs.

In conclusion, in the 18th and 19th centuries, even though Japan was isolated from other parts of the world both in politics and in science, merchants and natural scientists who worked for the Dutch East India Company brought back various materials concerning the natural history of Japan. Through Holland, those materials were eventually utilized by the European biologists. Among those materials, the illustrated drawing book called *Umi no sachi*, which contains fish and marine invertebrate drawings, played a significant role as a media, which provided important information and descriptions of the species living in and around the unknown country at that time. Cuvier and Valenciennes used *Umi no sachi* as source information in their ichthyological work, and some of their scientific names are still valid today. Férussac and d'Orbigny also used drawings from *Umi no sachi* for providing images of some squids and octopuses. European natural scientists in the early 19th century thus utilized the book brought back by the merchants as a reliable source material for their scientific works.

Acknowledgements:

I would like to express my appreciation to many people who kindly supported my research. I am particularly grateful to Alice Lemaire, conservateur au service du patrimoine, Bibliothèque Centrale du Muséum National d'Histoire Naturelle, Paris, for my research of the manuscript in the library. I greatly appreciate Tetsuo Yoshino, University of the Ryukyus, for all of his supports, offering me important source materials and his valuable comments based on his broad knowledge of natural history. This work was especially supported by the Sasakawa Scientific Research Grant from The Japan Science Society, and in part by a Grant-in-Aid for Young Scientists (B) (22700842) from the Ministry of Education, Culture, Sports, Science and Technology, Japan. My participation in the 4th International Conference of the European Society for the History of Science was funded by the Sasakawa Grants for Science Fellows from The Japan Science Society.

JAROSLAV PETRBOK AND FRANTIŠEK LEXA –ORIENT AND THE BALKAN PENINSULA TRAVELS[1]

Adéla Jůnová MACKOVÁ
Univerzita Karlova, Prague, CZEH REPUBLIC
mackovija@volny.cz

Abstract

The Balkan Peninsula was sometimes considered a gateway to the Orient. This impression lingered well into 20th century. In the same time, Balkans became a favourite holiday destination for Central Europeans. What happened if travellers-cum-scholars visited both places, the Balkans and the Orient?
Jaroslav Petrbok was a primary school teacher in everyday life. However, as a researcher he worked for the National Museum in Prague as geologist and paleoanthropologist. In the 1920s and 1930s he undertook scientific travels to the Balkan Peninsula and to the Orient. He organised research trips to the Orient and another trip to the seaside of Bulgaria and France (with detours to Istanbul or Tunisia) for teachers and their families. He gave talks about these countries and about his research, which were held for scholars as well as for general public.
František Lexa, studied Egyptology as an autodidact and mathematics at the University, first he was active as a grammar school teacher, later as an Egyptologist, and in 1925 he established the seminar of Egyptology at the Charles University in Prague. On his travels, including a trip to Egypt, he was devoted to research and spent considerable time obtaining study materials for his students. Lexa used his journey to Egypt in 1931 for improving his lectures for students of his Seminar. He took many photographs of monuments, their details, hieroglyphic script and objects from the Cairo museum. His travels however included also holiday journeys to Bulgaria with his family.
Both of them observed the "real" Orient, and the Balkans.

Jaroslav Petrbok

Jaroslav Petrbok (1881–1960) was born in Prague, obtained secondary school education for teachers and was employed as a teacher at primary schools in the area of Prague. He cooperated with the National Museum in Prague in

[1] This research was granted by GA ČR, č. 409/09/0295 project Českoslovenští vědci v Orientu 1918–1938 (Czechoslovak Scholars in the Orient).

capacities of geologist and paleoanthropologist. He became well known researcher in malacozoology, specialising in the Tertiary and Quaternary mollusks.[2]

He made scientific research and organised travels abroad during his specially funded paid holidays from September 1922 until August 1928. From September 1928 he worked again as a teacher, because the State School Council was no longer able to provide funds for him. Consequently he obtained only a few study days, and travelled during the summer holidays.[3]

Jaroslav Petrbok loved travelling and was on the road whenever he could. He wanted to know foreign countries, and study their cultural and natural wealth. He undertook his journeys with nearly no money, but he saw himself as different from just another of many globetrotters of his age, wandering penniless around the world for fun. He was, and perceived himself as being, a researcher working in Palestine, Egypt or Iraq, and in addition he organised travels for teachers to improve their knowledge about oriental countries, in other words he was a pioneer in specialised study trips.

The documents concerning the journeys are very rare. Papers of Jaroslav Petrbok are preserved in the National Museum archives. We can use his correspondence, scrap-archives (his own articles), and his book *Jewish ethics and work in Palestine*[4] His passports are preserved in the records of the Police Headquarters Prague, Section II, general records[5].

Travels to the Balkan Peninsula

Jaroslav Petrbok travelled very often to Bulgaria because of his geological and paleontological research. During 1914-1949 he undertook altogether 15 trips. During these mainly paleontological researches he found many Palaeolithic sites and further encouraged archaeological research in Bulgaria. No doubt friendly relations of the Balkan states with new Czechoslovak republic contributed to this activity.

He also organised summer school camps for secondary school teachers and their families in Yugoslavia and Bulgaria. From 1924 he tried to establish an organisation of teachers – scouts. In one of his articles from Czechoslovak *Teacher's magazine* he wrote:

> "Holidays at sea ceased to be a rich man's privilege, as camping and scouts organisations opened up possibilities for everyone including the least well off. Youth travellers can visit Asia Minor, Istanbul or Italy without difficulty, whereas not long ago these destinations were for privileged few, such as a professional traveller Kořenský. ... During my 1924 trip I observed carefully camping options and cheap eating out options (solid lunch for 4 to 5 piasters). In my experience it is best to compose the travelling group of people of approximately same social standing and education. Thus I would recommend teachers to organise their own scout inspired organisation, independent and not connected to existing groups, which are often in a state of litigation."[6]

Petrbok planned two types of trips. First series included camps near the sea in Bulgaria with a trip to Istanbul, or camps in France with a trip to Tunisia. Both of these summer travel series were prepared for teachers and their families. Trips to Istanbul and Tunisia were planned for several days to enable as much sightseeing as possible. We know from existing archived records that travels to Bulgaria took place for sure in 1925 and 1926. Second series of trips was planned only for adults and young adults as study trips through Middle East.

Travels to the Orient

In 1924 Jaroslav Petrbok undertook his first research journey to Palestine. During this time and during the next two expeditions he worked on Quaternary molluscs. In January 1926 Petrbok got a subvention of 5,000 CZ from the Ministry of Education to undertake a three month study journey to Palestine. Thanks to this financial support he added also research work in Syria and Egypt,[7] and finally, in 1936 he was also working in Iraq.

Petrbok used his knowledge of the countries he visited to organise trips for other teachers. A first travel was held in 1926[8], at an approximate cost of 3,000 CZ (compare it with the salary of Petrbok – 1820 Kč)[9] and took 6 weeks. They

travelled by train to Constanta in Romania, where they boarded a steamship to Piraeus. They spent three weeks in Athens and its surroundings, and on Peloponnesus. The travel was supported also by the Greek Ministry of Culture; they had free accommodation, a guide and discounts for train tickets.[10] Then they continued by a steam-ship to Egypt to visit Alexandria and Cairo, and later to Palestine and Syria. We can consider this journey as a really educational journey including Greece, Syria, Palestine and Egypt. This journey was aimed at providing the teachers with an opportunity to meet ancient and modern monuments of these great civilisations and to transmit this first hand knowledge to their students.

There were also further travels in 1928 and 1929; these were opened for everybody, were more expensive (4,000 CZK), took less time (3 weeks) and included only Egypt and Palestine.[11]

These travels were a sort of predecessor to travel clubs that organised travels to the Orient from the early 1930s. Also club travels were sometimes organised to acquaint middle class public, including teachers, with the ancient civilisations but also the reality of life in Orient in the first half of the 20th century, including the Zionist movement in Palestine whose work was admired by Jaroslav Petrbok. He was also preparing talks illustrated with slides about visited regions and about his work. The talks were given to general public in Prague and in other places in Czechoslovakia. Petrbok actively promoted and spread the idea that Oriental travel is a part of education now accessible to most. However, when travelling, he also used some approaches close to package tours (discounted travel), albeit in more rudimentary conditions of camps, and with governmental support, as his trips were meant to emphasize the strong educational element.

His research activities were manifold and Petrbok's paleontological, prehistoric or ethnographic collections were deposited in the National Museum.

František Lexa

František Lexa (1876-1960), studied Mathematics and Physics at Charles University in Prague. He became interested in hieroglyphic script and he started to study Egyptology in private. For a long time he continued earning his living as a teacher at a grammar school. In 1907 and 1908 he studied in Berlin with the Egyptologist Adolf Erman and Coptologist Carl Schmidt; he spent the next year in Strasbourg studying demotic script with Wilhelm Spiegelberg to improve his linguistic skills.[12] In 1925 he founded a seminar at Faculty of Arts in Prague and began to teach Egyptology. In 1927 he became professor of Egyptology and in 1958 he co-founded the Czechoslovak Institute of Egyptology in Prague together with his pupil professor Zbyněk Žába. Lexa functioned in many institutions; he was a member of the Academy of Sciences, Oriental Institute, as well as Ski Club or Club of Czech Tourists. Clearly, Lexa's interest in travel went in many directions.

The seminar of Egyptology had in its beginnings only a very small library inherited from the Institute of History of Art and complemented with Lexa's own library. Lack of material for students and necessity to know ancient Egyptian monuments better were main reasons for Lexa's trip to Egypt in 1930/1931. He also tried to get a job there, because after the death of professor Spiegelberg there was a possibility to work for the Egyptian Museum in Cairo. Lexa had to ask many official institutions to grant his journey planned for four months. He obtained funding from the Oriental Institute (15,000 CZK), Ministry of Education (20,000 CZK) and President T. G. Masaryk (10,000 CZK)

Lexa was working very hard in Egypt. He had only a few months to travel through the entire country and he duly visited archaeological sites between Alexandria and Aswan. His research started in Cairo, in the Egyptian museum, where he spent plenty of time. For Lexa the museum was a rich mine of knowledge, as well as a source for wonder. In his letter from January, 1st he wrote to his wife:

> "Surely you remember the statues of Rahotep and Nofret. They have dark grey eyes, so real, so lively, that when I saw them for the first time my heart missed a beat. They make an impression of a living soul being concealed behind them. And the wonder went on. Djoser's wife carrying chair ..., jewellery of Senusrets and Amenemhets, ... golden falcon ... all these are so fine and exquisite that any modern gold work cannot but look crude next to them. My head reeled and after my first visit to the Museum I decided to spend at least a fortnight in Cairo only to study everything in detail. Archaeological objects must be seen; photographs fail to convey the right impression."[13]

Lexa made numerous glass slides for his students. He photographed well known statues and other antiquities as well as details with hieroglyphic text or ornament. He worked in libraries, photographing interesting texts and pictures in books

that he did not have at his disposal at the Prague University. In his collection of glass slides (approximately 1200 pieces) there are also pieces that were bought in photographic studios in Cairo; for example slides of objects from the tomb of King Tutankhamen.

He also visited the surroundings of Cairo; he was really excited to see the Pyramids in Giza:

> "The afternoon was spent with Mr Hais and his sister-in-law, seeing the Pyramids. New wonder; I imagined their greatness, and was afraid of being disappointed. The pyramids however, were exceeding expectations. They may fail to impress people who have no knowledge of mathematics, physics and geometry, but if you know something of the subjects, you are just wondering about what knowledge the builders must have possessed to be able to make the monument. It would have been a sin to go to Egypt unprepared – half the enjoyment would be lost.[14]

After visiting Cairo, Lexa continued further south to Luxor and Aswan, and he spent a couple of days in Deir el-Medina with his pupil and colleague Jaroslav Černý, who was then working for French Institute of Oriental Archaeology excavations. Lexa visited famous tombs and temples of Upper Egypt, made many photographs of these monuments and bought large amount of smaller antiquities.

> "I bought some antiquities, small and less so, in Luxor, and had a box made for them, which I sent together with my suitcase back to Cairo, to the embassy, where it would wait for me…"[15]

In one of his letters he comments on the gradual development of his skill in recognising and evaluating objects of Egyptian origin:

> "If I learnt to understand Egyptian antiquities in the Cairo Museum, then in Luxor I learnt to tell real antiquities from forgeries, that is, if it is at all possible, for there are pieces of craftsmanship so perfect that it is impossible to tell a fake from the real thing."[16]

František Lexa spent in Egypt nearly four months visiting ancient Egyptian monuments and collecting material for his students and for his own research. On the way back to the north he stopped at other archaeological sites and from Cairo he made a trip to Fayyum oasis together with Czechoslovak travellers František Foit and Jiří Baum. For a couple of weeks he became a member of the Czechoslovak community in Egypt, took part in the meetings in the salon of the Hais family in Cairo, and made lectures on Egyptology for them. Lexa used his new experience and material for his lectures at the university, e.g. he started with a lecture on archaeology and continued in his linguistic lectures using his own photographs and slides of ancient Egyptian inscriptions and many other details.

We can see many different reasons for Lexa's travels. His Egypt trip was professional, and aimed at improving his Egyptological knowledge. Furthermore, he was travelling to European countries to study Egyptian antiquities and inscriptions in museums. This travel pattern is not surprising in the 20th century; however, for a man who started his career as one of the grammar school teachers in Austro Hungarian monarchy for whom travel would be, if anything, part of leisure or family life, extensive professional travel was a new chapter.

Eventually, František Lexa was also travelling abroad to enjoy his holidays. He had many interests. He was an enthusiastic tourist and skier. He often made trips to the mountains and he loved especially Bulgarian mountains, which brought him to the Balkans. Lexa visited Bulgaria for holidays only. We can follow his tours to the seaside as well as to the mountains until the late 1950s, when he was climbing the Pirin range (Vichren 1958).

František Lexa made a great collection of materials from his journeys. He donated his Egyptian antiquities to the National Museum in Prague; in these days they form a part of the Egyptian collection of Náprstek Museum and part of the collection of the Prehistoric department of the National Museum. Photographs and postcards from his Egyptian journey are still in a possession of his family, that takes part on our project to preserve them for future generations of Egyptologists.

EUROPEAN VOYAGES AROUND THE LAPLAND EXPEDITION (1736 -1737)

Abstract

The proposal focuses on the previous travels in different parts of Europe of some of the participating members of the concerned mission. This scientific travel was organized by the French Académie Royale des Ssciences, jointly with a similar mission to Peru, and was proposed in order to obtain a definite response to Newton's theory of gravitation after measurements made in France from the north to the south of the kingdom. Before their mission to Lapland, several participants visited England, Basel to be informed about the gravitation theory and implications. A new small English instrument was added to the equipment used in the measures in Lapland. Following this mission, further international cooperation and research settlement resulted for participants of the Lapland expedition, including other scientific travels in Europe.

The Lapland expedition is one of the two large expeditions ordered by the Académie Royale des Sciences in Paris in the 1730's to solve in a definite way the question of the figure of the Earth. This question was becoming very hot as there was some discrepancy between the flattening of the Earth deduced from measurements and experiments with the pendulum and the theoretical flattening deduced by Newton (1643-1742) and Huygens (1629-1695), both from different arguments. Newton used a result obtained by Jean Richer (1630-1696) in 1671 –the pendulum was slower at Cayenne than at Paris–: he inferred that the force of gravity was lower at Cayenne and explained this result, following his theory exposed in the *Principia Mathematica*, by the Earth being not a true sphere but a slightly oblate body (i.e. flattened at the poles). Huygens' argument was somehow different and implied all the bodies where there was a central force in $1/r^n$ –where r is the distance of a centre of force– situated at distance r from the figure of revolution –the Earth like an orange for both of them. These results contradicted those of Jacques Cassini (1677-1756) and his colleagues who, from local measured variations of degrees of latitude with latitude in France along the Paris Observatory Meridian line, deduced that the Earth was shaped like an elongated revolution ellipsoid; to explain theses discrepancies, some observers pointed out the possibility of observational errors, due to the precision of the instruments.

The Academy was very busy on that question and weekly debated both on the oblate or prolate "figure" of the Earth and the arguments and on what observations to complete to obtain a definite answer.

To be short, it is likely that in 1733 a young Academician, Charle Marie de La Condamine (1701-1774), while attending some meeting where the best ways to infer the actual shape of the Earth were being discussed, suggested a scientific expedition into a region far from France, where the variation of the length of a degree on a meridian line would be larger that in any measurement in France; the Academician Louis Godin (1704-1760) was ordered by King Louis XV and the Minister Comte de Maurepas (1701-1785) Secrétaire d'État à la Marine, to lead a measurement mission in Equator (now Peru); two other academicians were elected to participate in this voyage: La Condamine and Pierre Bouguer (1698-1758). This mission left La Rochelle and sailed for South America in May 1735.

Another Academician, Pierre-Louis Moreau de Maupertuis (1698-1759), following a visit to London in 1728, started a strong fight against the Cartesian mechanics and the ellipsoid Earth flattened at the equator inferred from the observations of the French astronomers, mainly Jacques Cassini (1677-1756) in position in the Observatoire Royal in Paris. Maupertuis attending the meetings of the Academy persuaded Minister Maurepas to plan a second scientific expedition, in the most distant place from the equator, in the polar regions; this second voyage was ordered in november 1735. With the help of a Swedish astronomer of his friends Anders Celsius (1701-1744), Maupertuis and the autorities, the Academy and the Royal Institution, elected a region near the Gulf of Bothnia in Lapland where the future measurements would be performed.

The participating persons to the Lapland expedition were Pierre Louis de Maupertuis as the leader; Alexis Clairaut (1713 -1765), an outstanding mathematician and a prominent French Newtonian whose calculations should be quite useful in the interpretation of the observational data; Charles-Etienne Camus (1699-1768), very skilled in experimental mechanics and time questions; Pierre-Charles Lemonnier (1715-1799), a very young Academician known as a very talented observer since he assisted his father Pierre Lemonnier (1675-1757); Abbot Reginald (or Regnauld) Outhier (1694-1774), elected correspondent of the Academy in 1731, considered too as a skilled observer –he had to write the log of the expedition. His book, the *Journal d'un voyage au nord en 1736 et 1737*, published in Paris in 1744, is a very pleasant and informative chronicle of the everyday expedition with many details about the astronomical observations and their organisation, about the people met by the travellers from Paris, about the cities and landscapes they went through.

One considers that this voyage definitively resolved the question about the figure of the Earth, the measurements completed in Lapland implying some flattening at the poles of the Earth.

Some voyages achieved by some participants to the Lapland expedition look like archetypes. The focus is on Celsius and Maupertuis' case, since they were the only ones who travelled abroad before the Lapland expedition (with the exception of a two months stay of Clairaut in the 1734 fall in Basel at Bernoulli's home following an invitation by Johan Bernoulli (1667-1748) possibly due to the influence of Maupertuis); another point is that their two voyages differed greatly in the aim and the way.

In a first part, the main abroad travels completed before the Lapland expedition will be presented; the travels following the northern mission will be discussed in second place.

Before the Lapland expedition

Pierre Louis Moreau de Maupertuis (1698-1759). Maupertuis was born in Saint-Malo (France). His family, thanks to his father's occupations in commerce and responsibilities in Brittany, acquired some influence and wealth. Maupertuis was first educated by his mother at home, then in Paris at the famous Collège de la Marche where he was taught mathematics by Guillaume LeBlond (1704-1781). Very young he showed a strong interest in mathematics and navigation; after a short stay in Holland, he came back to France as a volunteer for a musketeer company in Lille, he spent his free time working mathematics. As he was getting bored in the Army, he gave up this military career and came back to Paris. There he enjoyed some intellectual life with writers, mathematicians, musicians and carried on working on different mathematical questions with academicians as Guisnée (?-1718) and François Nicole (1683-1758). In December 1723, Maupertuis was appointed as adjoint- mécanicien member in the French Royal Académie des Sciences, to which, one year later, he submitted his first scientific paper: *«Sur la forme des instruments de musique»*; a second one was submitted in 1726: *«Sur une question de maximis et minimis»* ; he was 26 years old. These two papers show how extended his field of investigations was.

The following years, Maupertuis was abroad; he made two voyages of main importance to both his future scientific activity and his personal life. In 1728 he sailed to London where he met collaborators or scientists influenced by Isaac Newton (1643-1727, ns), who had just passed away. Maupertuis adopted quite immediately the Newtonian natural philosophy and held many meetings with prominent Newtonian figures such as Samuel Clarke (1675-1729), Henry Pemberton (1694-1771), and John Desaguliers (1683-1744). These mathematicians and philosophers either worked with Newton or taught and published books about the new Newtonian theory. Maupertuis became one among the first Newtonians in France and was very probably the most enthusiastic supporter of this new theory; all his future activity, in natural philosophy, mechanics and astronomy, was therefore changed. When he left London, since he had understood that studying the mechanics of Newton and the likely implications implied some improvement in his mathematical education, Maupertuis came into contact with Johann Bernoulli I (1667-1748), then a prominent senior teacher in the University of Basel. It followed a first stay in Basel with Bernoulli's family, during some months from 1729 to 1730. This first stay in Bernoulli's home was the beginning of both a fruitful collaboration and a very strong friendship. It is known that Maupertuis would die in 27th July 1759 in the arms of Johan Bernoulli (1710-1790), the third son of Johann Bernoulli I. More than ninety letters between Maupertuis and the Bernoulli familly are in the library of the Basel University, which show evidence of this strong and fruitful relations with the Bernoulli's family.

Quite different is the travel completed by ***Anders Celsius (1701-1744)***: a «grand tour» in Europe. Celsius was born in a scientist family; the Celsius «dynasty» was rich in astronomers and mathematicians. Celsius' grand-father Magnus Celsius (1621-1679) settled his observatory at home; he was professor of mathematics and astronomy in Uppsala University since 1668; during the 1664-1665 years he observed comets; his main published works are *Dissertatiuncula de cometis* (1665), *Tractacus de mundo visible* (1672), and *Dissertatio de cumparatione corporum ceolestium ad tellurem* (1672). Celsius' father Nils Celsius (1658-1724) had a tenure in Uppsala University, where he taught astronomy, mathematics, geography, poetry, and prose; his main published works are *De principis astronomicis propriis* (1679) and *Calculus astronomicus super theoria solis* (1685); Nils Celsius is known to have computed, in 1705, an Easter date a week too late. Anders Spole (1630-1699), the other grand-father of Anders Celsius, was too a prominent astronomer of his time: in 1688, he was appointed as professor in the newly created Lund University, where he equipped an astronomical observatory; later in 1679, he came to Uppsala as a professor, where he taught mainly about trigonometry, spherical and general astronomy, geography, optics, navigation, chronology, and ecclesiastic computes; Anders Spole founded a new observatory with new instruments (telescopes, quadrants), he observed the «Great» comet of 1680; he travelled abroad making his own «grand tour», from 1664 to 1667, and had meetings with the most renowned astronomers and philosophers of his time: Christian Huygens (1629-1695), Mercator, Robert Hooke (1635-1703), Robert Boyle (1627-1691), Jean-Dominique Cassini (1625-1712), and Giovanni Riccioli (1598-1671). Anders Spole presided over many dissertations and wrote textbooks, either in the *Acta* of the Swedish Academy or in the English *Philosophical Transactions*, the oldest scholarly journal in the modern sense. Most of these persons did travel from one university to another in Europe.

Anders Celsius showed very young some talent in mathematics and natural philosophy; in 1728 he was appointed professor in Uppsala, where he stood for Samuel Klingenstierna (1698-1765) then abroad. His first written work was published both in the Swedish academic *Acta* and the *Philosophical Transactions*; the following reference papers indicate the large field of his interest: 1724 publication: *Experimentum in argenti-fodina Salana circa ascensum Mercurii in barometro institum (Acta literaria Sveciae, 1724, p599-600) and (Phil. Tansactions,vol.33, 1724-25, 313-314)*; 1730 Publication: *Nova Methodus distantiam solis a terra determinandi* (resp. Marten Strõmer).

Celsius was granted by the Uppsala University autorities, to perfectionate his different skills, to meet European colleagues, to visit the most famous observatories and «scientific» universities and last, to acquire modern instruments; therefore he organised his European "Grand Tour" from 1732 to 1736, while carrying on his own astronomical observations and publishing on different subjects.

During this four year "Grand Tour" Celsius visited four countries: Germany, Italy, France and England; he departed from Uppsala in August 1732. From August 1732 to August 1733 Celsius was in Germany; in Berlin he attended some lessons by Christfried Kirch (1694-1740), director of the observatory where he completed some astronomical observations, mostly on the solar eclipse of 13 May 1733.

At the end of May he went to Nürnberg via Leipzig and Wittenberg, where he met Michael Adelbulner (1702-1779), a famous printer later teacher in mathematics and physics; both of them decided to create an astronomical newsletter, on which Celsius collaborated quite efficiently from 1733 to 1735. During his stay in Nürnberg in 1733, Celsius published a book related to auroral phenomena (northern lights) observations that he had collected: *CCCXVI observationes de lumine boreali ab a. MDCCXVI tad MDCCXXXII partim a se, partim ab aliis, in Suecia habitas,* collegit Andreas Celsius. While in Nürnberg, Celsius made astronomical observations with a new quadrant by the instrument maker Johan Ernst Esling from Berlin.

In August 1733 Celsius left to Italy. There, he visited Venice, Padova, Bologna, where he remained eight months, and finally Rome. He met Martin Folkes (1690-1754) Vice-president of the London Royal Society, and Giovanni Poleni (1683-1761), professor of astronomy, philosophy, and mathematics from Padova; Poleni was a talented scientist fellow of the London Royal Society and other academies. While in Bologna, Celsius worked and made some astronomical observations with Eustachio Manfredi (1674-1739) and Manfredi's assistant Eustachi Zanotti (1709-1782). Some of these observations were completed either in the observatory (here he used a mobile new quadrant and two mural ones) or in St Petronio Cathedral (where he used the big meridian line on the pavement in the Cathedral); some observations were photometric ones, and other related to the obliquity of the ecliptic. These observations were reported in the *Histoire de l'Académie Royale des Sciences*, 1735, by Dortous de Mairan (1678-1771) and in a publication of Bologna. In Rome, Celsius carried on his photometric observations, completed some verification of the Meridian Line in St Maria degli Angeli and observed the partial solar eclipse of 3rd May 1734 (the description of this observation is in the Philosophical Transactions 1738).

Celsius went to Paris in August 1734, being accompanied by Francesco Algarotti (1712-1764), a writer and philosopher who later, in 1737, published a very illuminating book about the Newtonian theory: Neutonianismo per le dame (this book had two translated editions: in French in 1738, *le Newtonianisme pour les Dames*; in English as *Theory of light and colors* in 1739). In France, Celsius had discussions with academicians and got in touch with some of them, specially Pierre Louis Moreau de Maupertuis, a strong support of the theory of Newton. He entered the group of Newtonians. He attended many heated sessions in the Académie Royale des Sciences where were debated the shape –the «figure»– of the Earth and the available observations to definitely solve the related question. Celsius participated in the final choice and organisation of the future astronomical and geodetic expedition, far from France in northern Europe that was to be led by Maupertuis.

During the summer 1735 Celsius sailed to London; there he got in touch with the prominent philosophers and Newtonians of the time: Hans Sloane (1660-1752), naturalist, collector, patron of science, the president of the London Royal Society after Newton; Cromwell Mortimer (1730-1752), Edmund Halley (1656-1742) and James Bradley (1692-1762). At that time, Celsius knew that he was going to participate in the Lapland expedition with Maupertuis, and tried to have the best instruments, as did the other expedition to Peru: The question «did Celsius obtain the new octant by John Hadley (1682-1744) which was acquired and used by Pierre Bouguer (1698-1758) in the Peru expedition, the related expedition ordered by the Académie Royale des Siences to solve the same question that the expedition to Lapland had to do?» has not a definite answer at the moment. During his stay in London, Celsius received letters fom Maupertuis worrying about the instruments which had been ordered to the most skilful English instrument makers, particularly a pendulum with the equipment to use it and a sector which had to be delivered before the departure to Lapland. In that aim Celsius met some of the Londonian instrument makers: George Graham (1675-1751), John Hadley (1682-1744) and John Ellicot (1706-1772). He made some astronomical observations and had some training in the use of the new instruments. The *Philosophical Transactions* report about observations of boreal auroras and of a lunar eclipse made by Celsius in Mr. Graham's house in London. Celsius left England and sailed to Dunkerque (France) in April 1736 to join his colleagues of the Lapland expedition in their way to the North.

After the Lapland expedition

A last mission was ordered to the four Academicians: a new measurement of the length of a degree of meridian between Paris and Amiens (this measurement had already been completed by Jean Picard in 1671) with the Lapland expedition instruments by using the same modus operandi: measurement of the distance between the two places, then measurement of the amplitude of the meridian arc.

It resulted that the degree measured in Lapland by the Academicians was 123 *toises* larger than the one measured by Picard. To be short, the question of the figure of the Earth was solved.

Maupertuis and Celsius followed different ways after the Lapland expedition. Whereas Celsius returned to Uppsala after his absence of five years, Maupertuis could not stay in France.

Celsius returned to Uppsala

There, in his university, he had to complete his many professor duties: teaching, thesis, lobby and success to establish the new and modern observatory in Uppsala; he was busy with its instrumental equipment, with the organization of the scientific activity of the Societas Scientiarum, with the completion of stellar catalogues; with the continuation of his own research on stellar photometry; with the definition of a new calendar as in other places in Europe (this question would lead to the new style calendar adoption in Sweden in 1753, after Celsius' death); with the definition of the thermometer temperature scale (the «Celsius scale»): 100° water freezing point, 0° water boiling point (this scale will be inverted later under the influence of Linnaeus (1707-1778). Coming back to his country, he had a very fruitful activity. He died quite young, aged 43, in 1744.

Maupertuis in Berlin

Before the Lapland expedition, Maupertuis had a very rich social life, enjoying, joking with a lot of friends, publishing many works; but due to his strong fight against Cartesianism and his strong support to Newtonianism, he made «enemies» very easily. When he came back from Lapland his relations with many other Academicians were still not pacified. The «older» Academicians in Paris, mainly friends of the Cassini, were still reluctant about the new theory of mechanics, and about the measurements obtained in the North during the Lapland expedition which meant a flattened Earth at the poles in opposition with the observational results of the Cassini Dynasty's measurements.

The return from Lapland was quite difficult, with many critics about the operations; Maupertuis, very early after the return to Paris, carried on a lengthy correspondence with Johann Bernoulli –a monthly letter, the postal car left Paris to Basel every Monday morning– and explained his operations, his results (a letter was sent from the Zuidersee as he sailed back to France), he visited his friends again in Basel to clarify his method and the results.

After some long discussions inside and outside the Academy, Maupertuis was quite disapointed, frustrated; the Lapland expedition results had been very questionable. In spite of all the explanations and verifications completed during the expedition, the «classical astronomers» , with Jacques Cassini (1677-1756) as a leader, went on in suspecting the quality of the measurements. As there were difficulties with the Académie Royale des Sciences, Maupertuis went on in different travels: to Saint- Malo, his youth town where he was happy to meet his family and he was confident of recovering a good health by breathing fresh air; in Cirey, near the independent region of Lorraine, where, in the château, lived the famous female scientist Gabrielle Émilie Le Tonnelier de Breteuil, Marquise du Châtelet (1706-1749) and, since 1734, his friend François Marie Arouet, known as Voltaire (1694-1778), who discovered Newtonism in London where he had been in 1728 to avoid a stay in the Bastille Royal jail. Both Mme du Châtelet and Voltaire needed a teacher in mathematics. Essentially, Mme du Châtelet did, as she was undertaking to make a French translation of the *Philosophiae Naturalis Principia mathematica* (1726 edition); her translation, *Principes mathématiques de philosophie naturelle*, published in Paris in 1756 (after Mme du Châtelet's death) permitted an easy diffusion of this work in Europe to a large public. Voltaire was among the first admirers of Maupertuis.

In the year 1739 three European kings would admit Maupertuis in their court or Academy to benefit of his knowledge and his renown: the kings of France, Russia and Prussia.

In 1746 King Frederick the Great (1712-1772) appointed Maupertuis as president of the new Académie Royale des Sciences et des Belles Lettres in Berlin; here, from 1746 to 1759, he could work with the most famous mathematicians and philosophers of the time. It seems that Voltaire (1694-1712) was the first to suggest to the future king of Prussia, in 1738, that his friend Maupertuis was the right person to run his new academy according to his wishes. Maupertuis met Frederick for the first time during the Prussian-Austrian war; Frederic, always in front of his army, went from one battlefield to another and Maupertuis followed trying to get meetings on the status of the Academy. In Berlin, as President of the Academy, Maupertuis had a quite tremendous activity: administration, organization, nomination of academicians, scientific research, publication of many works. The story and the results of this more stay of more than ten years in Berlin are not to be presented here.

In spite of his bad health (which, from some letters sent to Bernoulli in 1733, was already so before the expedition in the northern conditions), Maupertuis could stay and work in Berlin until May 1756. At that time he came back to Saint- Malo to try to recover from illness; it was the time of a European war and the two countries, Prussia and France, fought as enemies, which made Maupertuis quite unhappy.

After a long travel from Saint-Malo to Bordeaux, Lyon, and finally to Basel, he died in 1759, in Bernoulli's house, in the arms of his friend.

* * *

These two people, Maupertuis and Celsius, were very prolific, each of them in their own field. They were not the only ones to travel in Europe and to settle for some time in another country. Their travels were quite different: one of these two travels may be considered as a «grand Tour», since Celsius visited many places in Europe, met a lot of different persons – just a few names were indicated in this report–, used different instruments, and lastly, this acquired experience was to give advantage to the Uppsala Observatory. At the opposite, the other one, Maupertuis, had few very close friends –the Bernoulli family– who during his whole life would help him (with the exception of Voltaire, who later will be a terrible enemy); when Maupertuis left Paris to work in the new Academy in Berlin, a huge task was waiting for him.

Celsius became very famous as participating to the Academician mission to Lapland, which later made it easier for his attempts to modernize the Uppsala Observatory in his country, which he did not leave any more. At the opposite, after the success of the Lapland Mission, Maupertuis, very disappointed with some reactions in Paris, left his country and for about ten years he built a new life in another country, another family, another King. In Berlin he met many other mathematicians and philosophers from the whole Europe. The worries he wanted to leave in Paris might have found him in Berlin.

MATHEMATICS IN THE JESUIT COLLEGES IN SPAIN IN THE 17TH AND 18TH CENTURIES

Agustín UDÍAS
Facultad de Ciencias Físicas, Universidad Complutense de Madrid, SPAIN
audiasva@fis.ucm.es

Abstract

Jesuits established a network of colleges in Spain which reached 126 in the 18th century. According to the Ratio Studiorum mathematics should be included in the philosophy programs of all Jesuit schools. In contrast to other European countries, Spanish Jesuits showed a certain resistance to fulfil this requirement. Explicit mention of mathematics professors are only recorded for the colleges of Madrid, Barcelona, Cadiz and Calatayud. The longest list is that of the Colegio Imperial of Madrid from 1627 to 1767, but of the 23 professors only 13 were Spaniards. In the other colleges, with the exception of Cadiz, teaching mathematics began in the middle of the 18th century. Teaching was centred in geometry during the first years, and later in algebra with the introduction of differential and integral calculus in the last years before the expulsion of Jesuits from Spain in 1767. The professors of the Colegio Imperial, where two chairs of mathematics were established in 1625, left a number of published books and unpublished manuscripts. Among the Spaniards excelled José Zaragoza and Tomás Cerdá, who proposed the publication of a series of mathematical textbooks. Some foreign professors were della Faille, Richard, Petrei, Wendlingen and Rieger. Mathematics were given a special importance in the Seminarios de Nobles of Madrid, Barcelona and Calatayud, founded in the middle of the 18th century. The contents of the teachings can be followed from the Conclusiones Mathematicas, the published programs of mathematical dissertations by students of the Seminario de Nobles and the Colegio Imperial of Madrid between 1704 and 1762. In them we can find when modern mathematics was introduced as well as the acceptance of the Copernican system and Newtonian physics.

Mathematics in Jesuit colleges

The most influential figure in introducing mathematics teaching in Jesuit colleges was Christopher Clavius (1537-1612), professor of mathematics in the *Collegio Romano* between 1567 and 1612. We must remember that, then, mathematics included also astronomy, optics, mechanics, music and any other science where mathematics was applied. During the years 1580 to 1593, Clavius insisted in the need of teaching mathematics in all Jesuit colleges in the programs of the three years dedicated to philosophy. He defended that mathematics was necessary for understanding natural philosophy, taking a position that was introduced by the proponents of modern science. Among his writings defending this position are: *Ordo servandus in addiscendis disciplinis mathematicis* and *Modus quo disciplinae mathematicae in scholis Societatis possent promoveri*. He took part in the composition of the norms that were to regulate the studies of all Jesuit colleges, known as the *Ratio studiorum*. Clavius contributed to the inclusion of mathematics in the three versions of the *Ratio*: in the first of 1586 in the chapter on mathematics (*De mathematicis*) and in the second of 1591, and the final of 1599 in the rules for the professors of mathematics (*Regulae professoris mathematicae*). In the final version of the *Ratio*, mathematics was included in the program of studies of the second year of philosophy. Professors of mathematics were to be in all schools which had programs of philosophy. At least, it was established that the programs included Euclid geometry, astronomy (*sphaera*) and geography. The *Ratio* recommended also the creation of an academy of mathematics (*Academia rerum mathematicarum)* for the most interested and able students, where more advanced topics were treated. These academies were to serve for the training of future professors (Lukacs, 1986). The norms of the *Ratio* concerning mathematics were, in general, well received and accepted in most colleges in Europe, and in the about 600 colleges 92 chairs of mathematics were established (Fischer, 1978, 1983).

The situation in Spain

During the composition of the *Ratio*, the norms about the teaching of mathematics got in Spain a rather negative reception. Some commentaries sent back to Rome on this subject were: "The teaching of mathematics is here neither necessary nor possible"; "One cannot find adequate professors"; "Other subjects are more necessary and of greater use in the Society"; "In Spain mathematics is of none or little use"; "For our students its utility is very small"; "It will be enough that the professor of philosophy explain a little of astronomy when teaching Aristotle's *De Coelo*". These comments give an idea of the little interest that Spanish Jesuits had about the subject and the little interest also in Spanish society. However, the answer from Rome to these comments was that in all colleges where there was a program of philosophy, teaching of mathematics was obligatory (Lukacs, 1992).

In Spain in the 18th century there were 126 colleges, most of them founded in the end of the 16th and beginning of the 17th century. With full programs in philosophy, were those of Alcalá de Henares, Barcelona, Calatayud, Gandia, Girona, Granada, Madrid, Medina del Campo, Monforte, Palencia, Palma, Pamplona, Salamanca, Sevilla, Valencia and Valladolid. According to the norms established in the *Ratio*, in these colleges there should have been professors of mathematics. However, in spite of the norms, very few colleges had specific professors of mathematics which figured with this title in their professor lists (Udías, 2010).

The only colleges with appointed professors of mathematics were, in fact:

- Madrid, *Colegio Imperial*, 1627-1767.
- Cadiz, *Colegio*, 1689-1702.
- Madrid, *Seminario de Nobles*, 1734-1767.
- Barcelona, *Seminario de Nobles*, 1756-1767.
- Calatayud, *Seminario de Nobles*, 1756-1767.

This doesn't mean that mathematics was not taught at all in the other colleges, but probably it was done at a very elementary level, so that no special professors were needed and classes of mathematics, if existed, were handled by professors of philosophy. The programs of philosophy were based on Aristotelian philosophy. It is possible that at least some elements of geometry and arithmetic and some fundamental notions of astronomy were taught to complement the teaching of natural philosophy, specially Aristotle's treatises of *De Coelo* and *Meteorologica.* We don't have evidence of this, since no written documents have been found of such lectures.

The *Colegio Imperial* of Madrid

The most important exception to this situation was the *Colegio Imperial* of Madrid (Simón Díaz, 1952). A small school existed in Madrid since 1572, which grew very fast so that in 1598 it had about 750 students. In 1609 it was newly founded with the name of *Colegio Imperial* under the patronage of the empress Mary of Austria, daughter of Charles V and wife of Maximilian II. The school was raised to the category of *Reales Estudios* (Royal Studies) by Phillip IV in 1625, with university level, though it could not confer academic degrees. Since 1627, it had two chairs of mathematics among a total of 17 chairs. This was more than any university in Spain had at that time. From 1627 to 1767, there were 23 professors, of whom 10 were not Spaniards. They came from France, Belgium, Scotland, Switzerland, Bohemia, Italy and Austria (Udías, 2005). Difficulty in finding professors of mathematics among Spanish Jesuits show the little interest they had for this subject. There was, however, a need to fill the two chairs created by the royal founding with experienced professors. The first four professors were all non-Spaniards: they came from Switzerland, Belgium, Scotland and France.

Among the non-Spanish professors, the following deserve a special mention (Udías, 2005). Jan Karel della Faille (1597-1652), born in Antwerp (Belgium), was disciple of Gregory of Saint-Vincent and had succeeded him as professor in the University of Louvain. He was professor in Madrid in 1629-1647. He was specially interested in the problem of the determination of the gravity centre, and published *Theoremata de centro gravitatis* (1632). Hugh Semple (1589-1654) was born in Scotland and was professor in 1630-1640. He published a general textbook about the different subjects included under the heading of mathematics, *De mathematicis disciplinis* (1635). In this book he defended that mathematics was a true science, in the Aristotelian sense of the term, against philosophers who denied it. Claude Richard (1589-1664), born in Omans (France), occupied the chair for the longest time, 1630-1664. He was specially interested in geometry and published a commentary to Euclid's books, *Euclidis elementorum geometricorum* (1645), and another to the books of Apollonius on conic sections, *Apollonii Pergaei conicorum* (1665). These were not textbooks for the students, but advanced treatises. Jakub Kresa (1648-1715) was born in Smrzice (Check Republic) and professor in Madrid in 1686-1701. He published a translation into Spanish of Euclid's books 1-6 and 11-12, *Elementos geométricos de Euclides* (1689), intended to be used as a textbook for students. Johann Wendlingen (1715-1790), born in Prague (Check Republic), was professor in 1750-1767. Aware of the lack of good textbooks in Spanish, he published *Elementos de matemáticas*, 4 vols. (1753-1756). They covered at an elementary level arithmetic, geometry, trigonometry and logarithms. He was also interested in astronomy and made observations with telescopes. Christian Rieger (1714-1780), born in Vienna (Austria) was professor in 1761-1765. He had been professor of architecture in the University of Vienna before coming to Madrid and had published there two books on civil and military architecture: *Universae architecturae civilis* (1756) and *Universae architecturae militaris* (1756). In Madrid he taught mathematics, architecture and experimental physics.

Of the thirteen Spanish professors, two excelled for their production of published textbooks and their importance in the development of mathematics in Spain: José Zaragoza and Tomás Cerdá (Udías, 2005).

José Zaragoza y Vilanova (1627-1679), from Alcalá de Chisvert (Castellón), moved to Madrid from the school in Valencia where he had privately studied mathematics as he taught theology (Cotarelo Valledor, 1935). He occupied the chair of mathematics in the *Colegio Imperial* from 1670 to 1679. During this time, in order to remedy the lack of books about mathematics he conceived the plan of publishing a complete set of books covering all related subjects from arithmetic to astronomy. He published 12 textbooks of mathematics and astronomy in Latin and Spanish, among them: *Aritmética universal* (1669), *Geometría especulativa y práctica* (1671) and *Trigonometría española* (1672). His most important work was *Geometria magna in minimis* (1674), a book about the determination of the centre of gravity for plane and solid figures solved on purely geometrical methods.

A different character has his book *Tratado de la esfera en común, celeste y terraquea* (1675), where he presents the principles of spherical geometry, astronomy and geography. He presents the Copernican system, but due to the ecclesiastical censure, he adds that it can only be accepted as a hypothesis. He shows to know about modern authors, and defends the geo-heliocentric system proposed by the Italian Jesuit Giovanni Battista Riccioli (1598-1671) in 1651, a modification of Tycho Brahe's system, in which the Earth is at the centre, the Sun moves around it with Mercury, Venus and Mars rotating around it. He made also astronomical observations, specially, of the comets of 1664, 1665 and 1677. He is considered to be one of the most important figures in science in the Spain of his time.

Tomás Cerdá (1715-1791), born in Tarragona, was professor in the *Seminario de Nobles* (Barcelona) in 1756-1764 and in the *Colegio Imperial* (Madrid) in 1765-1767 (Gassiot y Matas, 1995). He was trained between 1753 and 1756 in science and mathematics in Marseille by Esprit Pezenas (1692-1776), Jesuit director of the observatory. There, Cerdá got in contact with the modern Newtonian science and mathematics. Pezenas had translated into French several works of English scientists, among them the mathematical works of Colin Maclaurin (1698-1746). As he returned to Barcelona, he brought these new ideas. Aware of the backwardness in mathematics in Spain, he proposed to publish a series of books covering from elementary arithmetic and geometry to the new developments of differential and integral calculus. He could only publish the first two books. *Lecciones de matemáticas*: vol. 1, *Elementos generales de arithmética y álgebra*; vol. 2, *Sobre ecuaciones* (1758). His career was cut short by the Jesuits expulsion of Spain by order of King Charles III in 1767. He left manuscripts of his projected books on differential and integral calculus and Newtonian astronomy that he was not allowed to take with himself to his exile in Italy. He was one of the first in Spain to teach differential and integral calculus and Newtonian mechanics and astronomy.

The *Seminarios de Nobles*

A special type of Jesuit schools were the *Seminarios de Nobles* (Seminaries for the Nobility), founded in the 18th century with the specific aim of training the young from the Spanish nobility (Martínez Escalera, 1993). There were four Seminaries: in Madrid, Barcelona, Valencia and Calatayud. Their programs didn't follow those of normal colleges, but taught what was thought to be necessary for a nobleman. Their programs included modern languages, history, mathematics, astronomy, experimental physics and also military training, dance, horsemanship and fencing. Those of Madrid, Barcelona and Calatayud had specific mathematics professors. The most important one was that of Madrid, founded in 1725 by King Philip V, and which had chairs of mathematics and experimental physics. The chair of experimental physics was a novelty and only existed in Madrid from 1757 to 1767.

In the *Seminario de Nobles* of Madrid there were professors of mathematics between 1734 and 1767. Among them we can mention Esteban Terreros (1707-1782) and the Italian Esteban Bramieri (1720-?). Terreros is better known for his dictionary of the Spanish language. His scientific work was his translation into Spanish of the work by Noël Antonio Pluche (1688-1761), *Espectáculo de la Naturaleza*, an encyclopaedic work of 16 volumes, in which he introduced the doctrines of

Descartes and Newton. The *Seminario* of Barcelona created a chair of mathematics in 1757, that was first occupied by Cerdá from 1756-1764. He was succeeded by Ignacio Campcerver (1722-1798) until 1767, except for a year that he spent in the *Seminario* of Calatayud. In the Italian exile he published *Bibliotheca mathematica* (1789).

Introduction of modern science and mathematics

The introduction of modern science and mathematics was delayed in Spain with respect to the rest of Europe. Newtonian physics and differential and integral calculus, which were generally accepted in continental Europe in the beginning of the 18th century, were not introduced in Spain until nearly fifty years later in the middle of the century. Since Jesuits were expelled from Spain in 1767, they had very few years to introduce the modern ideas in their teaching. To find out how they managed to introduce the new ideas in their teaching, we have to rely on the documents which are preserved in manuscript form mainly of the professors of the *Colegio Imperial*. When Jesuits were banned into exile from Spain in 1767, they were not allowed to take with them any of their books or manuscript notes, so they have been preserved in different archives. Those belonging to the professors of the *Colegio Imperial* are kept at the library of the *Real Academia de la Historia* in Madrid.

A search in these manuscripts has shown the approximate years when modern science and mathematics were introduced in the teaching of the *Colegio Imperial* (Udias, 2005). A manuscript on differential calculus with references to Euler and Wolff, titled *In methodum fluxionum introductio*, has been assigned with great probability to Rieger and may correspond to the period 1761-1765. This may be one of the first references of differential calculus in Spain. Cerdá promised in the preface of his published textbook a volume on differential and integral calculus. A set of manuscripts on this subject are clearly his work. Some of the notes use both Newton's and Leibniz' notation and give the resolution of simple differential equations. If they correspond to his teaching years in Madrid they can be dated about 1765-1767. The acceptance of the heliocentric system was complicated by the ecclesiastic condemnation on the book of Copernicus in 1616 and of Galileo in 1633. The system could only be taught as a hypothesis, not as the real situation. This ban was lifted in 1757 by Pope Benedict XIV. A manuscript of Rieger dated on 1763 clearly presents the heliocentric system. Cerdá left in manuscript form a complete text, *Tratado de astronomía*, in which Newtonian astronomy is clearly presented. This text is dated in Barcelona, 1760 (Cerdá, 1760, 1999).

The acceptance between 1704 and 1762 at the *Colegio Imperial* and the *Seminario de Nobles* of Madrid of the new developments in mathematics, astronomy and physics can be obtained from the programs of the organized public disputations on mathematics, cosmography and experimental physics held at those schools and published under the title of *Conclusiones mathematicas* (Udias, 2011). They were presented by students and presided by a professor. Twelve published programs between 1704 and 1762 are preserved, which show the progress of the introduction of modern mathematics and science. In mathematics in the period 1704-1748, the main subjects were geometry and arithmetic with very little algebra. For 1751-1765, the preponderant topic was algebra with elements of analytic geometry, and with the introduction of elementary differential and integral calculus with simple differential equations. In astronomy in the period 1704- 1734, still the geocentric system was proposed and the motion of the Earth denied. The Copernican system, prohibited by the Church, was presented, but only accepted as a hypothesis. In the program of 1740, the Copernican system was presented and no mention was made of its prohibition. In the last programs of 1748 and 1760, planetary motion was presented according to Newtonian astronomy, but ecclesiastical censure was still mentioned. In physics, modern developments were slowly introduced, for example, in the period 1734-1748, topics of magnetism, propagation of light and sound, and weight of the air were presented. In 1760, Newtonian gravitation, existence of vacuum, light and sound waves, and properties of electricity were presented. Though these may seem to be late dates in comparison with the rest of Europe, Jesuits were actually pioneers in their introduction in Spain.

Conclusion

Of the 126 Jesuit schools in Spain during the 17th and 18th centuries, only six had regular professors of mathematics. The *Colegio Imperial* (Madrid) had two chairs and regular classes of mathematics from 1627 to 1767. Half of its professors were foreigners. Of the Spanish professors only Zaragoza and Cerdá excelled. In the 18th century the *Seminarios de Nobles* of Madrid, Barcelona, and Calatayud introduced in their programmes mathematics and experimental physics. Modern developments of mathematics, astronomy and physics were introduced in their teaching only about the middle of the 18th century. This situation can be explained by the lack of social interest in Spain for mathematical sciences in the 17th and 18th centuries. To remedy this situation Jesuits were forced to bring professors from outside Spain. In spite of the delay, Jesuits were among the first to introduce in Spain the modern developments of mathematics and science.

OPTICAL INSTRUMENTS IN THE SERVICE OF GOD. LIGHT METAPHORS FOR THE CIRCULATION OF JESUIT KNOWLEDGE IN CHINA

Koen VERMEIR
Centre National de la Recherce Scientifique (CNRS), Paris, FRANCE
koen.vermeir@hiw.kuleuven.be

Abstract

The circulation of knowledge is accomplished by material means. Books and other written sources are often seen as privileged material bearers of knowledge, but other material objects are also suited for the distribution of practical as well as theoretical knowledge claims. In this paper, I will show how Jesuit authors were perceived to disseminate metaphysical and theological views by 'embodying' them in optical instruments. (I will understand this process of 'embodiment' in terms of the integration of scientific instruments, often accompanied by written inscriptions, in specific religious practices). Jesuits did not only promote their missionary work by preaching and by circulating theological volumes; they also did this by circulating material scientific objects through their vast missionary networks. In this paper, I will focus specifically on how the Jesuits' use of optical instruments was commented on by contemporaries (e.g. in Johann Christoph Wagners, Das mächtige Kayser-Reich Sina*, 1685). In the confrontation between the different parties in a religious controversy, otherwise tacit aspects of religious and technical practices become more explicit. This will give us a better understanding of the Jesuits' use of scientific instruments and their reception in a global context.*

Introduction

This paper is part of a larger project. I am interested in the relation between natural philosophy, mixed mathematics and religion in the early modern period. In particular, I want to look at how optical instruments were used in religious practices and how they acquired religious meanings. In this paper, I will look at *Das mächtige Kayser-Reich Sina und die Asiatische Tartaren*, a description of the Chinese empire, published by Johann Christoph Wagner in 1688. Wagner's book is an interesting case study, because the book is written by a protestant who based himself mainly on Jesuit sources. Furthermore, this book is published exactly at the moment of the Chinese rites controversy. This paper can therefore be considered a reception study of the Jesuit circulation of knowledge at a moment particularly fraught with confessional tensions.

In this paper, I will not only use the 'circulation of knowledge' as a historiographical concept. I also aim at studying the actor's own views on this circulation, and we should keep in mind this double use of 'circulation'. Wagner's book *Das* *mächtige Kayser-Reich Sina* is a description and an iconography of the Jesuit circulation of knowledge, from Europe to China.

This circulation is seen by Wagner through a specific lens, influenced by his protestant background and local context. At the same time, the book is itself the result of the circulation of knowledge back from China to Europe. It is a collection of data and narratives, based mainly on Jesuit descriptions, self-presentations and even propaganda, resulting in a very specific perspective on China.

Light metaphors and the frontispiece of *Das mächtige Kayser-Reich Sina*

Johann Christoph Wagner was born in 1640 in the German evangelical imperial city of Nürnberg. His father, Christoph Wagner, was cantor at the Lutheran Church of Saint Gilles (Sankt Egidien). From 1659 onwards, Johann Christoph Wagner studied at the famous University of Altdorf and in 1663 he held a disputation on his dissertation on astrological medicine, *De respectu corporum naturalium ad sidera in se agentia*, under supervision of Abdias Trew; and on the occult properties of seals, *De occultis qualitatibus et potissimum de sigilis*, under supervision of Johann Christoph Sturm. Later, Wagner would build a career as a popular writer in Augsburg. He wrote about other regions and cultures, about comets and he made calendars. Wagner, an evangelical Lutheran, moved around in a very difficult religious context, with Nürnberg and Augsburg located exactly at the changing frontline between Catholics and Protestants. *Das mächtige Kayser-Reich Sina* was a collection of the available knowledge on China presented in the vernacular. Wagner had never been to China, but his popular description was a compilation of diverse sources that he had consulted. He described the geography and the vegetation of the country, the cities, as well as the various dress habits and appearance of the inhabitants.

In this paper, I will focus on the frontispiece of the book, which represents a triumphal arch for the European arts in China. The Chinese, in this image, honoured the arts of Europe, brought to them by the Jesuit missionaries. The European arts depicted are part of mixed mathematics: gnomonics, statics, ballistics, hydraulics, optics, mechanics, music and geography. Mixed mathematics was generally seen as the focus of the teaching of the Jesuits. According to the Western reception stories, the Chinese admitted that they were behind in these fields and were eager to learn. The angel who places a cross on top of the triumphal arch symbolises that the study of these arts will in the end lead them to the true God.

For the purposes of this paper, I am interested in the upper part of the image. There, the four stages of knowledge are shown, as an adaptation of an older iconographical and philosophical tradition. William Ashworth's 'Light of Reason, Light of Nature: Catholic and Protestant Metaphors of Scientific Knowledge', published in *Science in Context* (1989), is a classic paper on this tradition. This paper is also a milestone in the study of scientific images as well as in the study of the use of early modern light metaphors. Note, however, that Ashworth claimed that he had found all copies of frontispieces that depicted such light metaphors, especially in relation to the light of nature and the light of reason (p. 104). Unfortunately, he missed Wagner's book on China. This is a pity, because I think the uses of light metaphors in this frontispiece give a very different view than those studied by Ashworth.

Let us start with the tradition as expounded by Ashworth. In *Retracing the Arts to Theology,* Bonaventura explains that there are four kinds of knowledge, which are hierarchically ordered, from lower to higher, as follows: (1) the light of mechanical art (external light), which include weaving, armour-making, agriculture, hunting, navigation, medicine and dramatic art; (2) the light of sense perception (lower light); (3) the light of philosophical knowledge (inner light); (4) the light of sacred Scripture (higher light). These ideas are visualised in a modified form in the frontispiece of the Jesuit mathematician and astronomer Christoph Scheiner's *Rosa Ursina sive Sol* (1626-30). One of the modifications that Scheiner makes is to change Bonaventura's 'light of mechanical art' into the light of the profane authorities. Athanasius Kircher also depicts the four sources of knowledge on the frontispiece of his *Ars Magna Lucis et Umbrae* (1646) as light effects. Again, Kircher makes some interesting modifications to the tradition. It should be clear that these works are likely sources for Wagner's frontispiece. There are interesting visual and iconographical similarities. It is not an accident that Wagner also refers to these four stages of knowledge. Furthermore, of course, Kircher's magnum opus on China was a dominant source to Wagner, from which he copied many images.

In contrast to the Catholic tradition of the four stages of knowledge, Ashworth argues that Protestants used light metaphors in an entirely different way. According to him, Protestants typically distinguish only between two kinds of light: the light of nature and the light of grace. Ashworth traces this use of light metaphors back to Paracelsus and Paracelsianism, and sees as an alternative source Francis Bacon. It is therefore, especially with protestant authors interested in the occult, that we find extensive use of light metaphors. Ashworth gives the example of Oswald Croll, who opposed in the frontispiece of his *Basilica Chymica* (1609) the two light orbs of nature and of grace. Another example Ashworth gives is Johann Daniel Mylius's *Opus Medico-Chymicum* (1618) and Johann Kunckel's *Ars Vitraria Experimentalis* (1679). Although Wagner is a protestant clearly interested in the occult (cf. his dissertation topics from 1663), in contrast to the sources mentioned by Ashworth, he distinguishes four lights of knowledge, and he is iconographically much closer to the Jesuits.

The conclusions that Ashworth draws from his analysis is that for the Jesuits, reason is the highest faculty, while for the protestants, the senses (as the 'light of nature') have priority in generating knowledge. There are some problems with

Ashworth's interpretation, however. Firstly, for many early modern authors, the light of nature did not refer to the senses, but to reason. Even if in some cases it might have referred to knowledge by sense perception, reason and/or intellect would still be involved. In many cases, it would therefore be wrongheaded to see the light of nature in *opposition* to reason. This is an anachronistic imposition of the historiographical construct of rationalists versus empiricists. Furthermore, for current historiographical sensibilities, Ashworth's argument is still too much framed in terms of the 'Scientific Revolution' or the Weber thesis. Lastly, Wagner provides an interesting counterexample to Ashworth's conclusions. Ashworth admitted to some difficult examples, e.g. the work of Hevelius and Scilla, but did not let them challenge his thesis. Wagner, however, is an interesting hybrid case that gives a very different view on the tradition of light metaphors and on the religious meaning of optical instruments.

The four emblems of knowledge

Let us look again at Wagner's frontispiece. The frontispiece was engraved by Melchior Haffner, an engraver from Ulm who worked mainly in Augsburg between 1670 and 1690. This engraver worked in both Catholic and Protestant visual traditions. Haffner engraved the frontispiece of the German edition of Kircher's *Phonurgia*, for instance, as well as the image of Ferdinand Verbiest's observatory in Peking, and many maps and travel journals in Asia. He was also the engraver of the allegorical frontispiece of Johannes Hartmann Medico-Chymica and of many portraits of Wittenberg theologians. The frontispiece of *Das mächtige Kayser-Reich Sina* is not chiefly the responsibility of the engraver, however, because Wagner explains in detail the important elements of the frontispiece in his text.

In the upper part of the frontispiece, we see the four cartouches that represent the four stages of knowledge. In this case, however, Wagner applies these four stages to the epistemic and religious development of the Chinese. In the first two figures, at the left, a lamp is depicted. The iconography is very similar to the lamp of profane knowledge in Scheiner and Kircher, with a hand coming out of the clouds holding a similar type of lamp. The novelty in Wagner's adaptation of this tradition is that the first lamp is closed, and that only the second one is opened. From the first, closed lamp, only a few dispersed light rays appear from the airing holes of the chimney. The caption of this image reads 'Es brennt zwar, aber leuchtet nicht' (it burns indeed, but it does not give light).

Wagner explains the first image in his text (Vorbericht, xxx^2/r) as follows. God has lighted the 'light of nature' (or the 'light of natural knowledge') in everyone, including the Chinese. It is clear that for Wagner, this 'light of nature' refers to knowledge that can be acquired by our natural means in general, and this term was not meant to divide between sense knowledge and reason. Until now, this 'light of nature' burned, but it did not give any light for the Chinese, because God blinded their unbelieving faculties. Their 'natural light' was closed by a thousand superstitions and vain doctrines. The truth remained inaccessible for this natural light, their leaders guided them blindly, and this is symbolised by the closed lantern.

The second cartouche depicts the same lantern, but a second hand opens the lantern. This is God's hand. Now, a shining light comes forth, so the Chinese can start searching for the Lord, and it becomes possible for them to feel and find him. It was God's grace to open the Chinese for the true religion. Evidence for this would be the recent missions of the Jesuits that have been successful in converting the Chinese. In the text, Wagner summarises this stage as 'So leitet Warheit das Gesicht' (In this way, truth leads our vision), but in the image, the caption refers more explicitly to the light metaphor: 'So leuchtet Warheit das Gesicht' (In this way, truth enlightens our vision).

At the right upper corner of the frontispiece, the engraver Melchior Haffner visualised the next two stages of knowledge. This iconography is striking. The third stage of knowledge depicts a magic lantern that projects a geometrical pattern. At this time, the magic lantern was still relatively new and unknown to the general public. Wagner was part of a local context in which the magic lantern played a significant role. When the engineer and instrument maker Johann Franz Griendel von Ach arrived in Nürnberg in 1670, he advertised his skills, including his aptitude in building a new instrument that 'shows everything that one desires'. There were regular demonstrations of Griendel's magic lantern in Nürnberg in the 1670s. Johann Christoph Sturm, who supervised Johann Christoph Wagner's studies in the 1660s, was fascinated by the magic lantern, and he demonstrated it in his lectures at the University of Altdorf in December 1672. He published a description and illustration of this 'curious recent invention' in his *Collegium experimentale* (Nürnberg, 1676, pp. 163-165). Wagner, who was still living in Nürenberg at this time, might well have been present at one of these occasions.

The instrument depicted in Sturm's text is a horizontal cylindrical lantern, a model introduced by Griendel. In contrast, the lantern on the frontispiece of Wagner's book is the traditional model with a vertical cylinder case. The design of the chimney and the case actually resemble most an illustration from Johannes Zahn's *Oculus artificialis teledioptricus sive telescopium* (1685). Zahn, who considered himself a pupil of Griendel as far as practical optics was concerned, described many magic lantern models in this book. The illustration in question can be found at the lower left corner on page 236 of Zahn's 1685 edition (p. 398 in the 1702 edition) and bears the caption 'Abscondita prodit et auget'. There is also a striking visual resemblance between the four emblematic shields with captions, in which Wagner depicted his light metaphors as optical instruments, and the four circular images with optical instruments, also with captions, set apart in Zahn's illustration.

Wagner calls the magic lantern the "Optical Lantern", after Griendel and Kohlhans, or also the "Art-Lantern". For him, this lantern symbolises the arts, and in particular the mathematical arts and sciences. Wagner writes that the Chinese are led to the knowledge of the true God by means of the mathematical arts and sciences, because these artful reflections will lead them from the created to the creator. This is what the magic lantern emblem, which bears the caption 'Die Kunst vergrössert dann das Liecht', shows. Wagner explains it in his *Vorbericht* as follows. A lens magnifies the light rays, like the arts magnify the natural light of reason. In the emblem, these light rays shine on a half circle, from which lines go to the centre, where a triangle is depicted. We can conjecture that this symbolises the following: the study of the wonders of nature leads to the origin of all things, i.e. God (the triangle stands for the trinity). In this way, Wagner propounds an interesting strand of natural theology, in which contemplation if the wonders of nature will lead us (and the Chinese) to knowledge of the true God. This is also the message of the frontispiece in general, with its depiction of all these mathematical arts and sciences, and the suggestion that they will lead the Chinese to the only true religion.

The fourth cartouche depicted at the upper part of the frontispiece is identified in the text as a camera obscura with a lens. Again, the iconography of this so called 'camera obscura' is striking. There is no dark room with a pinhole that might constitute a camera obscura. Rather, the whole scene is covered in darkness and it is unclear what the light source is. One might speculate that the image of the crucified Christ that stands on its head could be a light source of its own (a classical iconographic device, cf. Piero della Francesca's *Flagellation*), but there is no hint of such an interpretation in Wagner's text. Furthermore, the lens is far too big for a pinhole camera, even if we allow for some artistic exaggeration, as it has the same size as the represented crucifixion. This image seems to be inspired by several different images from Zahn's *Oculus artificialis.* The basic idea of the camera obscura that inverts a cross seems to be inspired by figure XVIII in Zahn, vol I, p. 160. Here we see an abstract representation of the basic elements of a camera obscura (object, pinhole and projection on a sheet) presented in front of a realistic landscape with a building, bridge and tree. The idea of the lens that reduces or magnifies a cross might be taken from an abstract representation of a cross that is inverted and reduced by a lens in Zahn, vol. II, p. 55. In Wagner's frontispiece, however, the cross is enlarged. Finally, the form of the lens in Wagner's cartouche looks very much like the lens represented by Zahn, vol. III, p. 238.

While the magic lantern represented the mathematical arts and sciences that the Jesuits introduced in China, the camera obscura stands for their religious teachings. Before, the Chinese despised Christianity, and Christ was only an executed convict. Now, thanks to the Jesuits, this perversity had been turned around. This process is symbolised by the camera obscura, according to Wagner, because this instrument turns around the cross, which was inverted, by means of an optical lens, and restores it. The caption of this cartouche reads 'und wird das Heil so auffgericht', 'and salvation (Christ) is erected in this way' (in the text, this variation is given: 'So wird das Heil auch aufgericht'). The inverted cross that is turned around by the camera obscura comes to represent the turned beliefs of the Chinese that are set right by the Jesuits.

Conclusion

The four cartouches on the frontispiece of Johann Christoph Wagner's *Das mächtige Kayser-Reich Sina*, depicting optical instruments, represent four stages of knowledge. The first stage is the natural light, represented by a closed lantern. The second stage is grace, which opens the natural light for the Truth, and is represented by a lantern that is opened by a divine hand. The third stage is the arts and sciences, which magnify the natural light. In this way, the knowledge of nature will lead the way to God. This stage, of natural theology, is represented by a magic lantern which shines on a geometrical figure. The fourth stage of knowledge is revealed theology, in principle embodied in scripture, but in this case the stress is more on the dissemination by Jesuit religious education. It is only this stage which will lead the Chinese to knowledge of the true religion.

These four stages are represented by the captions, which are reproduced with slight variations in the introduction of the book, and which represent a short poem. These four stages of knowledge are hierarchically ordered, as in the tradition of light metaphors that represent the four sources of knowledge. These optical instruments now also represent progressive stages in time, however. Providence and grace are described as a historical process, and these four stages depict historical events: the progress of the Jesuit missions in China and the conversion of the Chinese.

On the one hand, the four stages of knowledge are an iconographic depiction of the circulation of knowledge between Europe and China by the Jesuits. The Jesuits' central goals were education and missions. These are represented in stages three (magic lantern) and four (camera obscura) respectively. Just like the magic lantern and the camera obscura are optical instruments for the transmission of light, the Jesuits are God's instruments for the transmission of the true faith. On the other hand, the iconographic depiction on Wagner's frontispiece is also the result of this circulation: it is a reception story of the Jesuits' activities in China and their self-presentation towards the European public. Wagner's book represents a remarkably polished representation of what the Jesuits were doing in China. It is strikingly unpolemical, given the context in which the book appeared (Counter Reformation, Chinese rites controversy).

The frontispiece represents an interesting mix of Jesuit and protestant iconography. On the one hand, Wagner distinguishes four stages or sources of knowledge, in accordance with the Jesuit tradition. Also the visual imagery resembles Jesuit sources, and many illustrations in the book are directly taken from Athanasius Kircher's work. On the other hand, the first two stages represent one form of the 'Protestant' distinction between the light of nature and the light of grace. Furthermore, stage three can be interpreted as a natural theology, which was becoming very popular in protestant circles. The important role of the mathematical sciences, instead of observation and natural history, is again due to the Jesuit influence. Also, to avoid controversy, Wagner remains unclear on how and in how far we can obtain knowledge of God by pursuing the mathematical sciences. The stage of the magic lantern seems therefore ecumenical, which can be accepted by all parties. Stage four is the role of revealed religion, and although this of course refers to scripture, Wagner singles out the Jesuit teachings in China as the decisive factor in the conversion of the Chinese.

It should be noted that Wagner is not fixated by an opposition between the light of nature and reason. We should not interpret the light of nature as Ashworth suggests, i.e. as observation and sense knowledge. For Wagner, the natural light includes reason. Furthermore, stage three stands in particular for the mathematical sciences, and this stage is represented only as a magnification of the natural light of stage one. Stage three and four are the 'artificial' enhancement –by means of 'instruments' and education– of stage one and two, respectively. Wagner's representation of the four stages of knowledge by means of optical instruments innovates in the classical tradition of light metaphors of knowledge, and it is a fascinating example of the religious meaning attributed to optical instruments.

Maybe the most striking feature of these images, however, is that they fundamentally misrepresent the actual functioning of these instruments. These representations are plainly wrong. Firstly, the magic lantern is an instrument that projects and enlarges the image painted on a slide on a wall. In Wagner's text, however, the function of the magic lantern is only to magnify the light, like a spotlight. In the emblem on the frontispiece too, one does not see the typical rectangle with slides in the tube. Furthermore, the symbolic meaning of the magic lantern would change significantly if its projecting function would be taken into account. For Wagner, the sciences are supposed only to *magnify* the light of nature or reason. They are supposed to throw light on nature as it is. He would not want to add the projection of a painted slide, the projection of the philosopher's or mathematician's own imagination, to come into the picture. This, however, is the traditional metaphoric meaning of a magic lantern: the projection of one's own deranged fancies on the world in contrast to sober and truthful observation.

Secondly, the camera obscura without a lens gives an inverted projection. If one adds a lens, this is usually to get an erect presentation of an object. In the text, it seems that the function of the lens is misunderstood. Furthermore, the image in the frontispiece does not seem to be the image of a camera obscura. As I already argued, the image seems to be a compilation of different images from Zahn's book on optical instruments. If the illustration represents a camera obscura, the aperture is far too large, it should not contain a lens, and the projected image should be located in a dark room. Finally, it remains a mystery what the light source in this image might be –except for the inverted cross itself.

Is seems that both Wagner and the engraver of the frontispiece were not well informed about the technical aspects and working of optical instruments. These artefacts are not interesting in themselves to him. They only serve a representational function, and a way to extend the classical tradition of light metaphors for the sources of knowledge. Even if Wagner did not understand the details of optics, he wanted to expand on the iconographical and textual traditions of religious and epistemic meanings that were attributed to mathematical instruments. The religious meaning these instruments assumed in the seventeenth century is difficult to trace today, because the material artefacts do not speak and the textual traces are scarce. Nevertheless, these iconographical clues give us a glimpse of a very different religious world these mathematical instruments were part of.

THE JESUIT HONORÉ FABRI AND THE THEORY OF PROJECTILES

Michael ELAZAR
Max Planck Institut für Wissenschaftsgeschichte, Berlin, GERMANY
melazar@mpiwg-berlin.mpg.de; mikielazar@gmail.com

Abstract

The Jesuit Honoré Fabri (1608-1688) was a senior representative of Jesuit scientists during the period between Galileo's death (1642) and Newton's Principia mathematica *(1687). As I have shown in a paper published in 2008, Fabri managed to integrate into his impetus-based physics (and general Aristotelian framework) the principle of Linear Conservation of Motion, generally (and inaccurately) referred to as "inertia". Furthermore, Fabri also accepted Galileo's law of falling bodies, as long as perceptible times and spaces are concerned; he indeed formulated a different rule for "infinitesimal" moments, but he took pains to (successfully) show that for measurable spatial or temporal units his own law converged to Galileo's rule, i.e. the "odd numbers law". However, while thus accepting two key concepts of classical (or Pre-Classical) physics, Fabri flatly rejected Galileo's analysis of projectiles and dismissed the Pisan parabola as the solution for the projectile's trajectory; instead, Fabri employed an Aristotelian-flavoured principle –that nothing exists "in vain" (*frustra*)– and developed a different curve, which albeit being totally erroneous was closer to the trajectory actually observed than Galileo's parabola. My lecture will thus explore this unique case of scientific-theory dissemination, in which a member of the Society of Jesus reveals himself as keen on assimilating important "New Science" insights, but in his own terms: preserving an Aristotelian (or Neo-Aristotelian) spirit that demands theory to stay as close to observed facts, and cannot accept a mathematical abstraction which does not correspond to observed projectiles (i.e. the parabola, which as we know today is different from observed projectiles because of air resistance).*

The French Jesuit Honoré Fabri was born in 1608 and between 1640 and 1646 taught natural philosophy and mathematics in the Jesuit *Collège de la Trinité* at Lyon. This period is considered the most fruitful and brilliant in his career, and his writings were quite successful even outside the Jesuit order. In 1646 Fabri's career as a Jesuit College lecturer came abruptly to an end, when he was removed from teaching and transferred to a bureaucratic post in Rome. According to contemporary sources, Fabri was at odds with his Jesuit colleagues and superiors, who did not welcome his fondness for novelties (Lukens 1979, pp. 10-16; Heilbron 1979, p. 113). The removal of audacious Jesuits from their teaching posts was a common measure against those charged with introducing dangerously new ideas into the Jesuit classroom (Feingold 2003, p. 31); Fabri was indeed introducing Cartesian and Galilean principles "through the back door", so to say, while using the old and "legitimate" (so-to-speak) concept of impetus. However, as we shall see today, such assimilation of novel ideas did not imply unconditional assent. Fabri was deeply influenced by Galileo's and Descartes' inertial (or pre-inertial) thinking, and was not afraid to harshly attack Aristotle on this subject (a fact which must have irritated his superiors),[1] but he nevertheless strongly rejected (like most contemporaries) Galileo's analysis of projectiles, including the parabolic trajectories.

Fabri's physical system was centered around impetus, a concept introduced into scholastic physics in the 14th century, whose main purpose was to modify Aristotle's account of projectile motion: while Aristotle resorted to the medium as the factor explaining the continuation of motion of a projected object, Jean Buridan and his followers rejected this explanation and opted for a *vis*, or *qualitas* called impetus, which is impressed in a body and causes it to move (Clagett 1959, pp. 534-537). Fabri, in line with this scholastic tradition, defined impetus as a "quality" which causes motion in the subject in which it inheres, and like Buridan claimed that impetus is a "permanent" quality, and thus able to endure. However, contrary to the scholastic tradition, Fabri integrated his belief in the innate permanence of impetus, together with the uncontested possibility of motion in vacuum and the exclusive linearity of impetus, to explicitly formulate the principle of Conservation of Linear Motion. The scholastic protagonists of impetus still followed in Aristotle's footsteps by rejecting the possibility of terrestrial motion devoid of any resistance, and by retaining Aristotle's common dicta: that violent motion is inherently brief, and thus can never be imagined to be eternal, and that straight motion – whether natural or violent – can never be, by definition, *ad infinitum*: it must have both a *terminus a quo* and a *terminus ad quem* (Damerow et al. 2004, p. 264; Baldini 2004, p. 135). Even the young Galileo, in his *De motu*, claimed (like many scholastics philosophers) that impetus is a self dissipating entity, thus avoiding the conclusion that violent motion in vacuum might be eternal.

Fabri started by transforming Buridan's "permanence" of impetus to a genuine principle of conservation, insisting that impetus is conserved as long as nothing causes its destruction (Fabri 1646b, pp. 68-69). Furthermore, Fabri was highly influenced by those whom we now regard as the pioneers of modern science. Contrary to Buridan's impetus, which can be directed, either linearly or circularly, Fabri adopted from Giovanni Benedetti an exclusive linear impetus, and stated that circular motion is nothing but an impeded straight motion, which explains why a stone released from a sling tends to move along a straight line (Fabri 1646b, "Synopsis amplior", para. 1).

Fabri utilizes these two principles –the conservation of motion and the exclusive linearity of motion– in his analysis of motion in the void, which appears in an appendix to his book *Metaphysica demonstrativa* (Fabri 1648), an appendix entitled *De vacuo*. In this analysis Fabri exhibits a deep Galilean influence, and he is no doubt also inspired by Descartes and Gassendi. Fabri not only accepts there the possibility of motion in the void, but explicitly determines that violent motion in vacuum must be eternal, linear and with constant velocity. In order to illustrate this fact, he suggests some kind of a "thought experiment", resulting in what we would call inertial motion:

> If, while a stone moves upwards with a decelerated violent motion, everything else were to be destroyed, it would then never stop, but would move [upwards] with constant motion, namely retaining the same level of velocity which it had at that very instant in which the rest of the universe was destroyed.[2] (Fabri 1648, pp. 563-564)

Fabri now mentions Aristotle's four famous objections to the possibility of vacuum –presented, in *Physics* book IV, as so called "paradoxes" which allegedly result from the assumption of void. According to one of these objections, the assumption of void entails zero resistance, and therefore infinite velocity, and thus absurd instantaneous motion; according to a second objection, the same assumption would entail the ridiculous conclusion that bodies differing in weight and shape would move in the same velocity. Fabri flatly rejects these objections by showing that rather than consisting "absurdities" they accurately depict the behavior of bodies existing in vacuum; Fabri explicitly relies on Galileo's *Discorsi*, and adopts the proportion Galileo formulated there, which indeed allows for motion in zero resistance and determines that bodies fall exactly in the same rate in vacuum, no matter their weight or shape (Elazar 2008, pp. 15-19). Aristotle's last objection claims that if we permitted vacuum, then a body once moved would have no reason to stop moving (that is, an eternal violent motion would result; *Physics* [Aristotle 1930], 215a19). Fabri's reply to this objection is straightforward and decisive:

> I concede, of my own accord, that in a total void a stone once moved, would move forever, unless it is restrained extrinsically.[3] (Fabri 1648, p. 564)

Fabri regards the motion of a horizontal projectile as a "mixed motion" resulting from two impetuses: "natural impetus" directed downwards, caused by gravity, and an impressed horizontal impetus. In line with linear conservation of motion, he speculates what would happen to the projectile if it were weightless:

> If natural impetus did not participate in this motion, the projectile would obviously move along a straight line with constant motion.[4] (Fabri 1646b, p. 162)

---

[1] This issue is discussed in detail in Elazar 2008.

[2] "Si tamen dum lapis movetur sursum, motu violento retardato caetera omnia destruerentur, nunquam deinde sisteret, sed moveretur motu aequabili, retento scilicet eo gradu velocitatis, quem habebat eo instanti, quo reliquum orbis destructum est".

[3] "Concedo ultro fore, ut in totali vacuo lapis semel motus, semper moveatur, nisi ab extrinseco retineatur".

As already Alexandre Koyré noted, Galileo himself was never able to totally abstract an object from its weight, and only in the writings of his disciples can we find comparable statements, namely unequivocal announcements of linear conservation of motion (Koyré 1978, pp. 240-241). Furthermore, Fabri adopted Descartes' opinion concerning a projectile, that contrary to those who Descartes called the *docti* (namely, scholastic philosophers), the phenomenon which must be explained is rather the decay of its motion, not its continuity (Koyré 1968, pp. 72-73). However, the *answer* that Fabri gave to the question "why does a projectile stop moving", is entirely non-classical: it consists of a peculiar method of "patching up" again natural impetus in a non-inertial way that reveals strong Aristotelian (or scholastic) restrains. It is well known that Galileo assumed "superposition", i.e. the mutual independence of the two components, and easily proved that the inevitable outcome of compounding constantly accelerated fall with constant horizontal velocity would be a simple parabola. Fabri rejected Galileo's elegant solution, and replaced it with an original explanation which abolishes superposition, and assumes that these two components are not mutually independent. The explanation Fabri suggests derives from Aristotle's dictum that nothing in nature exists "in vain" (*frustra*), and as I will show, it serves Fabri to qualitatively define a curve which is similar to the parabola, but not identical with it, and describes the real motion of a projectile (so Fabri claims) somewhat better than Galileo's parabola; essentially, the explanation which Fabri posited replaced the reason given by the Galileans (and by modern science) to the conspicuous difference between the parabola and actual projectiles: I mean of course air resistance.

Why does Fabri reject Galileo's parabola? Essentially, for the same reason that the parabola as a projectile's trajectory was very unpopular among Galileo's immediate contemporaries, especially practitioners: it did not fit observed projectiles, and the discrepancy became worse as the projectile was faster. In Fabri's words, even a child playing with a discus can see that in projectile motion the arc of descent is much smaller than the arc of ascent, contrary to the symmetric parabola (Fabri 1646b, p. 169). But still, Fabri's main argument against Galileo might strike the modern reader as odd. Adopting Galileo's parabola, Fabri explains, would violate what he defines as "hypothesis 3". This is hypothesis 3:

> A horizontal projectile close to the end of its motion strikes less hard than at the beginning, indeed also a projectile thrown downwards at an angle. This hypothesis has been proved a hundred times, and cannot be cast in doubt.[5] (Fabri 1646b, p. 154)

Now, a "hypothesis" –according to Fabri– is not a tentative assumption, open to subsequent confirmation or rejection; rather, it is a qualitative statement drawn from sensible experience which is considered by Fabri entirely valid and suitable to serve as a premise for the subsequent deduction of theorems. According to Fabri, a "hypothesis" is always drawn from "the most certain experiments", and other examples for such hypotheses are "fire heats" and also "a heavy body falls with accelerated motion" (Fabri 1646a, pp. 86-90; Dear 1995, pp. 138-140).

Fabri's third hypothesis seems strange to the modern reader, who following Galileo's analysis knows that (under ideal conditions) even a horizontal projectile (let alone one thrown in a downward inclination) necessarily increases its velocity as it falls, and therefore strikes harder, not less hard, as the motion advances. However, it must be noted that the influence of air resistance is indeed strongly felt –even with relatively slow projectiles– so Fabri's hypothesis is less unreasonable than it might seem at first glance; it was actually rather common in the 1630's and 40's, and was expressed for example by Diego Ufano and Marin Mersenne, influenced by the Aristotelian dictum that violent motion always decreases with time. Fabri simply claims that adopting Galileo's solution –which entails a constant horizontal velocity and a constantly accelerating downward motion– would violate hypothesis 3 (Fabri 1646b, p. 160).

Here is the trajectory Fabri proposes for a horizontal projectile (see figure 43 inside figure 1). The lack of superposition is obvious in the gradual decrease of the horizontal distance acquired in consecutive instants (HI<GH<FG<EF). Furthermore, in order to make sure that hypothesis 3 is not violated, Fabri remarks that not only is the horizontal motion impeded, but also the acceleration downwards is not constant, but behaves like an inclined plane: it starts with zero, and gradually increases until it reaches the regular free fall acceleration (Fabri 1646b, p. 161). Accordingly, the perpendicular additions, PQ, RS and TV keep increasing with time. Fabri insists that this mutual inhibiting is necessary in order to prevent the resultant final motion from becoming higher than the initial velocity, thus violating hypothesis 3.

As we can see, the horizontal component of the projectile is gradually diminished; in his analysis of oblique projectiles (figures 47-49 inside figure 2), Fabri provides an explanation for the way in which this diminution occurs, based on the Aristotelian dictum that nature does nothing in vain. Look at the parallelogram in figure 48; it depicts oblique projectiles, but the mechanism is the same for horizontal projectiles. AD is the initial violent impetus, and AB is what Fabri calls "innate impetus", namely gravity. In order to see what happens to the violent impetus, we need to compound these two impetuses. Now impetus, according to Fabri, is inherently a scalar magnitude, so these vectors are supposed to add up to the scalar sum, AB + AD: this would be the case if they were in the same direction. However, according to the old parallelogram rule (from the pseudo-Aristotelian *Mechanical Problems*), the actual sum of these two impetus is the diagonal AC. Fabri therefore

---

[4] "Si impetus naturalis non concurreret ad hunc motum, proiectum moveretur per lineam horizontalem rectam, ut constat, motu aequabili".

[5] "Proiectum per horizontalem sub finem motus minus ferit quam initio, imo & proiectum per inclinatam deorsum; haec hypothesis centies probata fuit; nec in dubium revocari potest".

claims that the difference between the scalar sum and this diagonal is in vain, *frustra*, so this is the amount to be subtracted from the initial violent impetus: AB = DN in figure 48, so AN = AD + AB (the scalar sum); AC = AE, so EN = (AD+BC) – AC; FD = EN, which is the amount *frustra*, so AF (i.e. the violent impetus in the next iteration) = AD – FD (Fabri 1646b, p. 168). In the descending part of the motion the natural component – Fabri explains – is not constant but gradually increasing, therefore the overall traversed horizontal distance will be smaller than in the ascending part.

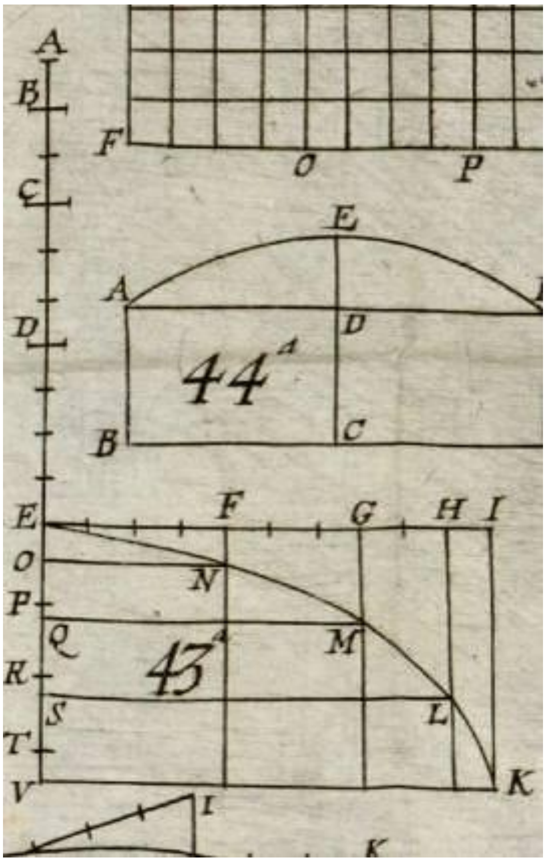

Fig. 1: Fabri's trajectory for a horizontal projectile
[File Fabri-figure-1.jpg; taken from Fabri 1646b]

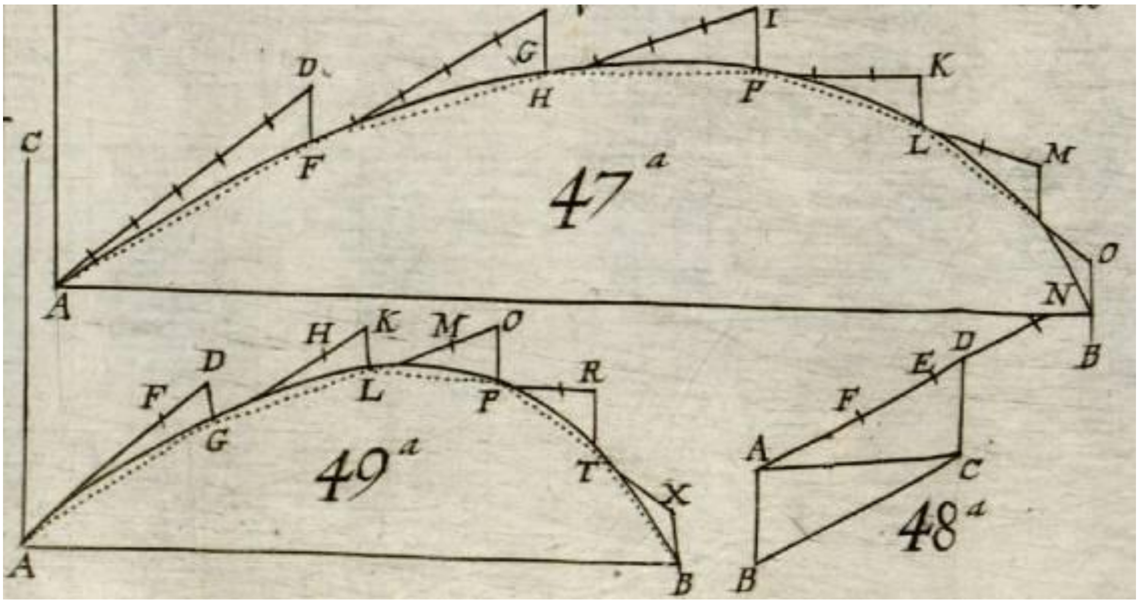

Fig. 2: Fabri's analysis of an oblique projectile
[File Fabri-figure-2.jpg; taken from Fabri 1646b]

Fabri rejects the Galilean explanation that it is air resistance which is responsible for the difference between the theoretical parabola and the observed trajectory, claiming (wrongly) that we hardly see any effect on the downward natural motion, while the violent motion is indeed affected; therefore, it cannot be the case –claims Fabri– that air resistance causes the projectile's retardation (Fabri 1646b, p. 160).

Fabri's rejection of Galileo's parabola is perhaps better understood in light of his general conception concerning the manner in which physics should be pursued. Here's Fabri's opinion on Galileo's achievements, pertaining especially to his theory of falling bodies, but also relevant to projectiles:

Indeed the Great Galileo, who before any one else wonderfully and with almost divine sharpness of genius led local motion to where no mortal had led it before (*Quidem prae caeteris magnus ille Galileus, qui mirifica, & fere divina ingeni iacie, motum localem eo perduxit, quo mortalium nemo perduxerat*); nevertheless because he omitted many things which relate to motion, as everyone knows, and did not prove those marvellous effects from physical principles, but only assented to some proportions from geometrical [principles]; in order to have regard for physics, we undertake another way: we do consult geometry, to explain and set forth those aforementioned proportions which belong to motions; but we reduce the effects connected to those proportions to physical principles; in other words, while we suppose what there is (*quod sint*), we prove why it is (*propter quid sint*). (Fabri 1646b, p. 5).

Elsewhere, in a letter to Mersenne, Fabri states that physics must employ mathematics, and stresses that its purpose is to reduce "sensible effects" (that is, effects perceived by the senses) to their causes; this time he does not attack the New Physics, but rather standard scholastic physics, deeming it a discipline "full of disputes", worthy of being called only "elementary metaphysics" or "superior grammar" (Tannery et al. 1945-1988, vol. XII, p. 276). Galileo, in other words, indeed merits praise for amply "consulting geometry", but he made the mistake of treating the geometric figure of a parabola –which does not depict an actual projectile– as a "sensible effect". Fabri, therefore, loyal to the new principles he adopted from the New Science (thus opting for an analysis in a vacuum, and clearly asserting Linear Conservation of motion), exhibits also loyalty to the Aristotelian ideal of *scientia*, which must involve a causal explanation of observable phenomena, namely reducing natural effects to their causes. Fabri is clearly trying to limit the scope of physics to "sensible", i.e. observable effects, and thus avoid Galileo's way of pursuing physics, which was conceived by Fabri and his contemporaries as nothing more than abstract mathematics, which does not pertain to real ("sensible") nature.

THE FIRST PROTESTANT MISSIONARIES AS EUROPEAN NATURALISTS IN INDIA –COMPETITORS OF THE JESUITS IN THE 18TH CENTURY

Brigitte HOPPE
Ludwig-Maximilians-Universitaet, Munich, GERMANY
B.Hoppe@lrz.uni-muenchen.de

Abstract

At the beginning of the 18th century (1706) the first protestant missionaries were sent to South India with the aid of a contract between the 'Waisenhaus'-foundation in Halle (Saale) and the King of Denmark. They had different contacts with Jesuits, the religious competitors but also supporters of activities with the same aim. Priests of both groups, trained at European universities, and in particular the protestant missionaries supported by missionary physicians sometimes, were scholars in many fields. They published Tamil translations of Christian religious texts and comparative textbooks on linguistics.

In one field the first protestant missionaries in India surpassed the Jesuits: Some of them became specialists in natural history and made extensive collections of Indian natural objects, which activities remained nearly unnoticed by the history of science until our days. The 18th century missionaries in India remained in correspondence with eminent European naturalists, who highly estimated the natural objects of the overseas regions, sending recent European publications on natural history to India, in order to support the self-training of the scholars, who trained also their disciples in Natural History in the overseas country. In the counter-move these sent their collections and observations to European partners who became sponsors for the missionary work. The historian states many ways of knowledge exchange between Europe and India from the 18th to 19th centuries and find traces of the spread of Indian natural history collections and manuscripts through whole Europe. In this way, these activities furthered much the knowledge of Indian civilization and the development of natural history in Europe from the 18th to the 19th centuries, during decades before Indian countries became members of the British Empire.

First steps of Jesuits into India

This paper will focus on missionary activities which remained neglected by the history of science. At first it remembers some well-known events of the beginning of Christian missions at the former East-Indian continent. After the fleet of Vasco da Gama (c. 1469–1524) had reached the West coast of India in 1498, the first catholic priests came together with the traders from Portugal to Goa. An intense colonial mission was initiated by the Jesuit Francisco de Xavier (1506–1552) since his arrival in India in 1542. He even brought the inquisition to Goa, which worked there from 1554 to 1774. This example was followed by several Portuguese Jesuits. They tried to convert people of the Middle Class in favour of Catholicism with the aid of privileges, but many 'rice Christians', not deeply convinced adherents, hated finally the Christian priests, trying to change Hindu religious practices such as burning the widows. Another problem arose during the 17th century, after the Jesuit Roberto de Nobili (1577–1656, in India since 1606) achieved to establish new mission stations in internal regions of South India, since he initiated an adaptation to the Hindu civilization. He hoped to diminish the European image of Christian religion and to win people of the lower casts with the help of Brahmans, but this strategy led to conflicts between missionaries and the Pope; thus, the 'controversy of rites' burdened the missionary activities, lasting until 1744. Nevertheless, many Jesuits worked in South India. One eminent representative was the Italian Costanzo Giuseppe Beschi, S. J., (1680–1747) who arrived in India in 1710. He followed the missionary objectives as a learned theologian and an eminent linguistic expert in Sanskrit, Tamil, and Telugu. He published grammars and a dictionary of the vernacular languages and wrote religious poetry, e.g. the poem *Têmbâvani*.[1]

Religious, linguistic, and literary activities of the first protestant mission founded in India

During the lifetime of this Jesuit similar aims, such as founding new parishes and Christian churches, educating converted persons to new priests and catechists, learning the regional vernacular languages, and writing religious texts in these languages, were followed by the first Protestant mission established in 1706 in India. It started its work at the East coast of South India at Tranquebar (now Tara(n)gambadi) in Tamil Nadu at the Coromandel coast.[2] This Danish trade place was situated in the colony of the only European Lutheran King, the pious Frederik IV (1671–1730). Since Danish pastors were not disposed to that mission, he appointed to work for the 'Danish-Halle-Mission-Society' German theologians trained by the 'Waisenhaus' (Orphan-House) in Halle (Saale) and ordained in Copenhagen, shortly before leaving Europe. Thus, the religious basis of that mission society was a group of strictly pious Protestants called the Pietists. They propagated the biblical fundament of Christianity and its practical realization by means of social works of charity and teaching in a world-wide perspective which they called "*Pietas universalis*".[3]

The first protestant missionaries, Bartholomaeus Ziegenbalg (1682–1719) and Heinrich Pluetschau (1677–1752, returned to Germany in 1711) arrived in 1706 and were followed by three colleagues in 1709, among others Johann Ernst Gruendler (1677–1720). They had to surmount many difficulties during the first years in India. Since their missionary objectives were much different from those of colonial politics, the trade authorities entertained distrust against the activities of charity including poor people of lower casts for inspiring trust to the Europeans. Nevertheless, after eight years the young priest Ziegenbalg achieved to finish the conflicts.[4] He attained toleration of the missionary activities for the next decades; thus, a very fruitful work was continued with the help of many followers.[5]

The priests were supported in the field of medical care by an indigenous medical man since 1712. Since he knew the health problems in the tropical region and the regional therapeutics and cures, his practice was relatively successful, during

the first years. Thereupon, for the health care of the increasing parish, other Europeans and indigenous people, a European physician was sent to the mission from the 1730s on. In 1732 Samuel Benjamin Cnoll (1705–1767), trained in Halle, launched into a successful medical practice, while he applied the European healing methods, and established a chemical laboratory where he produced the pharmaceuticals himself. This practitioner much engaged in empirical work did not write long medical treatises.[6] However, the manuscript *Der Malabarische Medicus*, a translation of a Tamil medical book, finished by the missionary J. E. Gruendler in 1711 and sent to Halle, reported on the indigenous medical practices, the principles and therapeutics. The missionary intended to let publish the experiences unknown to the Europeans as a document of the foreign civilization.[7]

Similar literary products on diverse subjects accompanied the mission work. Shortly after the arrival in India the missionaries began to study the native languages of the region, mainly with the help of an indigenous teacher. For communicating with other Europeans and also for teaching in the mission schools, later on, they used the Portuguese language. In Tamil, Telugu, and Sanskrit they produced translations of the basic religious texts –often using earlier writings produced by Jesuits– such as the Lord's Prayer, chapters of the Gospel (a first edition was finished by Ziegenbalg and Gruendler in 1714; a second edition was published by Ziegenbalg and Benjamin Schultze (1689–1760) in 1723), and hymns (Gruendler's 48 hymns in 1714). Moreover, the learned missionaries wrote several types of dictionaries and grammars, sometimes comparing expressions of different languages;[8] such writings should be helpful for training the future religious teachers, disciples of different types of schools established since 1707,[9] and also for European scholars. Such useful learned linguistic studies, supplemented by poetry, were continued by several missionaries until the 19th century, for example by B. Schultze, Christoph Theodosius Walther (1699–1741), and August Friedrich Caemmerer (1767–1837), the last 'Danish-Halle' missionary.[10] They furthered linguistics in Europe and stimulated studies of literature and native languages in India itself.

While the contrast between the Catholic Church personified by the Jesuits and the Lutheran confession produced the competition between both sides, the same scholarly interests became the basis for a kind of collaboration. Missionaries of both confessions compared their religious writings, in order to learn from one another, how to translate principal theological notions, such as 'God', 'heaven', 'Saviour'. The Protestants even helped the Jesuits to resolve a practical problem. They realized soon that the best way to spread their ideas was not only by preaching, but also by supporting it with the aid of printed booklets given to the people. Remembering the successful manufacture of book production at the Orphan-House in Halle, they established such a manufacture at the mission station.[11] This very rare equipment in former India missed the Jesuits at that time. Therefore, the learned brother C. G. Beschi asked the Protestants to print his new Latin-Tamil grammar in Tranquebar (1738). That was realized, but not without including some corrections annotated by the missionary C. Th. Walther.[12]

Protestant Missionaries as naturalists in India

In one field the Danish-Halle Missionaries surpassed the Jesuits: they contributed to the development of a scientific natural history of India in Early Modern Times; that area was unknown in Europe and carried out mainly with regard to useful applications in India during earlier times. They were active with respect to both, to gain knowledge on useful natural products and also to observe natural phenomena by collecting natural objects, unknown to European scientists. In contrast to the Jesuits they did not only pay attention by preference to natural products helpful as medicaments or useful as foodstuffs,[13] but based on the broad education in the Orphan-House in Halle, where disciples had been trained in some practical work and gardening, the Danish-Halle missionaries were interested also in natural phenomena and improved their knowledge by self-instruction with the aid of special books. In addition, they were stimulated by an external impulse, namely by the directors of the Orphan-House in Halle, demanding to send reports and documents of all kind of remarkable objects and phenomena different from European ones, but typical of the foreign nature and civilization. From the beginning on, the missionaries fulfilled this task, already starting on board of the ship, during the long shipping through the Cape of Good Hope. After having received the reports, the directors in Halle published them in the newly founded journal *Merckwuerdige Nachricht aus Ost-*

Indien (entitled *Hallesche Berichte*, later on), since 1706. With the aid of that journal accounts on India were spread through Europe, immediately. One effect was that many European citizens wanted to support the mission work and spent money to the Orphan-House.[14] By continuing that procedure of fund raising, the mission could work in India with the support of sponsors until the beginning of the 19th century, when the Napoleonic Wars shocked Europe.[15] Another effect of the publications was the reaction of interested scholars. Since trustworthy information from India sent by educated or even learned persons was extremely rare in Europe in the 18th century, it was much welcome by scholars. Some of them asked special questions directly to the missionaries.[16] Therefore, these intensified their efforts in the field of natural history, too. Several pastors became eminent specialists in this area. Some of their most important accomplishments, which are described in detail in my recent publications,[17] are to be appreciated by summarizing the details as follows.

The missionaries conveyed their observations by means of several ways: they sent reports continuously, often in the form of long letters, to the directors of the Orphan-House in Halle or to the superiors in Copenhagen or to learned personalities or personal friends in Europe; moreover, they communicated objects or special collections of natural objects, and manuscripts of treatises for publication to scholars in Europe. All kind of documents on meteorological, geographical, mineralogical, zoological, botanical, and, last but not least, ethnological phenomena are preserved now in archives, libraries, museums, and public collections spread through Europe. Many documents of correspondences, manuscripts, and sketches of objects besides some objects themselves are to be found in the archives of the Franckesche Stiftungen at Halle (Saale), of course. In addition, we found letters, manuscripts and in particular collections of herbarium plants from Copenhagen, Lund in Scandinavia, London and Liverpool in England, through Paris and the private Herbarium of E. v. Lindemann in 'Jelisabethgrad' (now Kirovograd in Russia), to several places in Germany, from Berlin, Goettingen, Jena to Munich (coming from the Herbarium of Johann Daniel Christian Schreber, 1739–1810, Professor at the University of Erlangen) and Regensburg.[18] Besides the herbarium parts in Berlin we have to mention the extraordinary special collection of preparations of Indian fishes in the Natural History Museum of Berlin, which was performed by Christoph Samuel John (1747–1813) and sent to the Berlin physician and zoologist Marcus Elieser Bloch (1723–1799), who included it in his publication (*Naturgeschichte der auslaendischen Fische*, 8 vols., 1785–1795).[19]

Some of the natural history observers excelled as research workers; they relied on a good school and university training in Germany, which they completed by means of self-instruction. As early as in the 1730s C. Th. Walther collected and compiled a herbarium of more than 700 Indian specimens, mainly spermatophytes (*spermatophyta*), by request of a physician and botanist at Hannover (Germany). Now, the sheets with pressed plants and plant parts are bound in 12 volumes entitled *Plantae Malabaricae*, forming a special collection of the actual Herbarium at the University of Goettingen (Germany).[20] Many handwritten labels of the specimens are kept; some original ones are palm leaf pieces with an ink inscription, showing the broad interest of Walther in the Indian civilization by mentioning the former Indian plant name in Tamil characters and Walther's Latin transcription; in addition, a paper label presents often pharmaceutical and economic applications in Latin and sometimes in German language.[21]

In the second half of the 18th century the scientific style of botanists switched from the pre-Linnaean methods to the rules of Linnaean plant research. That arrived relatively early in Tranquebar, since a former student of Linnaeus joined the mission. From 1768–1775 the physician and botanist Johann Gerhard Koenig (1728–1785) worked in the mission station before he was sent by European and Indian sponsors to research expeditions at different places in East Asia. Between his sojourns outside he visited the colleagues in Tranquebar several times, discussing with them botanical problems.[22] Those

arose during the collecting and classifying studies which the missionaries of the central station in Tranquebar carried out in the style of teamwork, unifying two generations of missionaries and their native disciples, during the period from c. 1780 to c. 1810. That very intense research work, stimulated by physico-theological ideas of the European Enlightenment,[23] was developed and improved by Christoph Samuel John (1747–1813), living in Tranquebar from 1771 on, and Johann Peter Rottler (1749–1836), who worked 1776–1803 in Tranquebar and subsequently in Madras. The team of naturalists was completed by the younger missionaries Johann Gottfried Klein (1766–1821), since 1791 the mission physician, and Benjamin Heyne (written also Hayne, Heine, 1770–1819), who lived as a physician employed by an Anglican mission society 1793–1819 in India, working in particular as a botanist 1802–1808; after staying only a few years in Tranquebar, he remained in contact with the missionaries. The connections between these naturalists are to be inferred from remarks in the correspondence and from the handwritten labels of herbarium specimens, which show for example a text handwritten by Klein and corrected by Rottler.[24] The scholarly partners in Europe of the research workers in India were the most eminent naturalists of that time. Koenig corresponded with Linnaeus and sent longer manuscripts and many plant collections to Anders Johan Retzius (1742–1821), Professor of Botany at the University in Lund, who let publish several manuscripts of the travelling research worker. John and Rottler were in touch with the superiors in Copenhagen and with the naturalists of the *Gesellschaft Naturforschender Freunde zu Berlin*, contacting especially the botanist Carl Ludwig Willdenow (1765–1812), moreover, with the *Naturforschende Gesellschaft zu Jena* and the *Regensburger Botanische Gesellschaft*. After having published papers in the journals, edited by these learned societies, and having sent natural objects to their members, both missionaries were honoured by being appointed members. Similar personal honours attained J. G. Klein and B. Heyne, too. Moreover, the research results of these missionaries were included into many publications produced by specialists in Europe from the end of the 18th to the middle of the 19th century. In addition, their collections became the basis of the most important publications on the flora and fauna of India worked out by British naturalists from around 1800 on. The names of the missionary collectors are mentioned in the entries of many specimens in the works published by William Roxburgh (1751–1815) (*Flora Indica*, 3 vols., 1795–1832) and Robert Wight (1796–1872) in his *Contributions to the Botany in India* (1834).[25] Finally, the collections preserved in European and Indian (in Chennai) herbariums have a special value because of containing many types or syntypes of Indian species; therefore, they are much esteemed until our days.

Conclusions

The mission in India achieved its principal religious objectives, while it contributed to the foundation of a Christian Church in India. Although the European competition between the confessions was continued in the foreign country, Jesuits and Protestants practiced some collaboration in secular fields. The inhabitants of the subcontinent, where many people of different origin were assembled, had to learn some tolerance against different religions and cultural traditions, in order to mastering the daily life.

The methodical basis of all missionary activities, religious and secular ones, was constituted by networks. One network was established between the missionaries and some European organizations and scholars; it was maintained by correspondences and exchanges of manuscripts, books and other objects. Another one was founded by the missionaries and natives of India, such as scholars, theologians of other religions and confessions, the rulers, but also pariahs. Special tasks, in particular natural history research, were accomplished by working as a team. Missionaries worked together with their colleagues having a university education; their collaborators were indigenous students and disciples, and they learned from Indian informants.

Through the channel of networking the Protestant missionaries contributed to a circulation of knowledge between Europe and India from the 18th to the 19th centuries. They exchanged knowledge on languages, literature, and all areas of civilization. In the field of natural history they brought not only European scientific methods and knowledge to India, but they stimulated changes of the European scientific knowledge by including natural objects and phenomena, appearing in a tropical region, into the international science of Modern Times.

"IN PARTE PHYSICAE THEORETICA NEWTONUM EIUSQUE COMMENTATORES SECUTUS SUM" –LEOPOLD GOTTLIEB BIWALD'S *PHYSICA GENERALIS* AS A COMPENDIUM PROPAGATING NEWTONIAN PHYSICS IN EUROPE

Cornelia FAUSTMANN
Recipient of a DOC-fellowship of the Austrian Academy of Sciences at the Institute of Classical Philology, Medieval and Neolatin Studies, Universität Wien, AUSTRIA
cornelia.faustmann@univie.ac.at

Abstract

Leopold Gottlieb Biwald's physics textbook in two volumes, Physica Generalis *and* Physica Particularis *(Graz 1767/1768), was very important in the 18th century. Widespread in whole Europe and officially designated for use at the universities and lyceums throughout the Habsburg monarchy by an imperial decree of 1779, it played an important role as a very up-to-date compendium propagating Newtonian physics. In his textbook Biwald, Jesuit and Professor in Graz (Austria) for decades, does not only refer to elements of Newton's theory itself but also to several Newton-commentaries and uses various Newtonian textbooks. Biwald's principal sources on the subject are compendia written by 'sGravesande, Keill, Maclaurin, Mako, Musschenbroek, Pemberton, and Scherffer. In this paper I analyze the Physica Generalis into which the most important elements of Newton's theory found their way as an example of the propagation of Newtonian physics in Europe. Attention will be given to the following questions: Which sources are the most important for Biwald: Newton's* Principia*, Newton-commentaries or textbooks? Does Biwald focus on Jesuit sources when explaining Newtonian physics? Which is the geographical and cultural background of the authors of the Newtonian sources of the* Physica Generalis*? What does this aspect tell us about the (international) scientific (Jesuit) network in the 18th century and which new facets concerning the form of dissemination of the Newtonian theory in Europe result from that? In which aspects is Biwald's textbook outstanding in comparison to its Newtonian sources, what are the author's own specific achievements? Hence, how can the success of the* Physica Generalis *be judged in the pan-European context?*

Leopold Gottlieb Biwald and his achievements in physics

Today Leopold Gottlieb Biwald is primarily known for his physics textbook, which played an important role in 18th century physics teaching. Biwald was born on February 26th, 1731 in Vienna (Austria).[1] On October 17th, 1747 he entered the Society of Jesus[2] and studied in Raab, Trnava, Vienna, Ljubljana, and Graz. After his ordination to the priesthood Biwald was employed as a Professor of Logic and Metaphysics at the University of Graz in 1763. From 1764 onwards he officiated as a Professor of Physics,[3] additionally he taught Natural History at Graz from some time later on.[4] For two times –namely in 1786/1787 and in 1798/1799– Biwald was the principal of the Lyceum of Graz,[5] into which the University had been changed.[6] When Biwald was 74 years old, Emperor Franz I. awarded him a necklace with a gold medal, which was an honor especially for Biwald's merits during his 42 year long teaching activity at Graz.[7] Shortly afterwards Biwald died on September 8th, 1805 in Graz (Styria, Austria).[8]

Considering that Biwald was the first Professor of Graz who was ever awarded such a medal of honor and that a bust portraying him with this medal was dedicated to him,[9] one can say that he was eminently important for the University and Lyceum of Graz respectively in the 18th and early 19th centuries. When it comes to the question of the highest significance of Biwald's works, his physics textbook in two volumes, entitled *Physica Generalis* and *Physica Particularis*, plays the most important role. This compendium, written in Latin and published in Graz in 1767/1768,[10] was published several times in quick

10 In the following, quotations are taken from the more influencial second edition of Biwald's textbook:
Physica Generalis, quam auditorum philosophiae usibus accomodavit Leopoldus Biwald e Societate Iesu, Physicae in Universitate Graecensi Professor Publicus. et Ordinarius. Editio Secunda, ab authore recognita. Cum speciali privilegio S. C. R. Maiestatis. Graecii, Sumptibus Iosephi Mauritii Lechner, Bibliopolae Academici. Typis Haeredum Widmanstadii, 1769.
Physica Particularis, quam auditorum philosophiae usibus accomodavit Leopoldus Biwald e Societate Iesu, Physicae in Universitate Graecensi Professor Publicus, et Ordinarius. Editio secunda, ab authore recognita. Cum speciali privilegio S. C. R. Maiestatis. Graecii, Sumptibus Iosephi Mauritii Lechner, Bibliopolae Academici. 1769.

succession, widespread in whole Europe,[11] and officially designated for use at the universities and lyceums throughout the Habsburg monarchy by an imperial decree of September 1779.[12] Biwald's textbook is especially characterized by an adequate composition of the material, by a presentation of the information in a didactically well deliberate manner, and by a very clear phrasing.[13]

Newtonian Physics in the *Physica Generalis* and Biwald's Newtonian sources

Regarding the reception of Newtonian Physics in the *Physica Generalis* there are a lot of chapters explaining Newtonian findings. This is not astonishing as Newton's authority in physics was beyond dispute at that time and as a major part of the *Physica Generalis* is devoted to classical mechanics (according to the usual practice of 18th century physics textbooks). So Biwald explains rectilinear and curvilinear motion, equilibrium of forces, collisions of bodies, gravitation, and celestial mechanics on the basis of the Newtonian theory.[14]

Apart from Newton's *Philosophiae Naturalis Principia Mathematica* Biwald also uses many other Newtonian sources in order to gain a preferably concise description in the *Physica Generalis*. He mentions several of those texts in the praefatio at the beginning of the *Physica Generalis*: so –except of the *Principia* – the commentaries on Newton written by 'sGravesande, Keill, Maclaurin, Musschenbroek, Pemberton, Sigorgne, and Paulian.[15] Additionally, Biwald uses further sources which he does not mention in the praefatio or even not throughout the whole textbook. As far as Newtonian Physics is concerned, two physics textbooks have to be listed: Paul Mako de Kerck-Gede's *Compendiaria Physicae Institutio* and Karl Scherffer's *Institutiones Physicae*.[16]

When the geographical circumstances of Biwald's Newtonian sources are considered, we see that most of them were published in Great Britain, namely Newton's *Principia*, of course, as well as Keill's, Maclaurin's, and Pemberton's

books. The main importance of commentaries on Newton published in Great Britain does not seem very astonishing as Newton's *Principia* were also published in Great Britain. However, there are also important works explaining Newton's theory which originated in other countries – in this connection especially the Netherlands have to be mentioned with 'sGravesande's and Musschenbroek's publications. Furthermore, two of the mentioned sources published in France have to be considered – namely Paulian's *Dictionnaire de Physique* and Sigorgne's *Institutions Newtoniennes*. Last but not least, further sources used by Biwald were published in his own country, Austria – regarding the reception and propagation of Newtonian Physics especially Mako's and Scherffer's publications have to be mentioned. Biwald's use of Mako's and Scherffer's textbooks is absolutely not surprising because both of them were Jesuits, contemporaries of him, and published their works quite shortly before the *Physica Generalis* in Vienna, not far away from Biwald's workplace in Graz. So the geographical distribution of these sources of the *Physica Generalis* shows a well working (Jesuit) scientific network in the 18th century. Within Europe there did not seem to exist any barriers which could constrain the reception of Newtonian Physics respectively of certain commentaries on Newton. On the contrary, when considering the dates of publication of Biwald's sources, it becomes clear that their reception happened proportionally quickly.

Within the scope of analyzing these sources the question of the languages also has to be taken into account. Six of the texts presented above are written in Latin (Newton, 'sGravesande, Keill, Mako, Musschenbroek, Scherffer), one Latin translation of an English publication is available (Maclaurin), one further publication is originally written in English (Pemberton), and finally Biwald uses two French sources when explaining Newtonian Physics in the *Physica Generalis* (Paulian, Sigorgne).[17] The predominance of Latin texts as Biwald's sources is not surprising as his compendium is also written in Latin. A more substantial question in this connection would be why Biwald used the Latin language for his textbook, the more so as vernacular languages experienced a significant upturn at that time. This issue can be answered by the context in which the *Physica Generalis* has to be classified – namely the Jesuit educational field, in which the use of the Latin language still was absolutely common.[18]

Another important aspect in this regard is the fact that Biwald did not only stick to Jesuit sources. Of course, there are certain obvious tendencies – such as the great significance of Jesuit physics textbooks and other Jesuit publications, e.g. Boscovich's *Theoria Philosophiae Naturalis*,[19] for Biwald –but we also have to note that Biwald equally uses non-Jesuit commentaries on Newton to a large extent– namely most of the sources quoted above originate from a non-Jesuit context (these are 'sGravesande, Keill, Maclaurin, Musschenbroek, Pemberton, Sigorgne, and Paulian).[20] So we can say that there are no confessional limitations as far as intertextual relations between the sources are concerned. Generally speaking, also when it comes to terms of content, Biwald presents the information in the *Physica Generalis* in an objective scientific way, which can be regarded as a modern method likewise from today's point of view.

The importance of different types of sources for the *Physica Generalis*

For analyzing the importance of the different types of sources for Biwald's textbook firstly a good impression is given by the total number of the authors and scientists mentioned in the *Physica Generalis*: Newton absolutely predominates with 58 quotations, followed by Boscovich with 38 quotations. Afterwards the Cassini family and Lalande (especially important for Biwald's astronomy) follow with 20 quotations each. Then Lacaille succeeds with 14 quotations. However, the most important Newton commentary for Biwald's *Physica Generalis* follows afterwards with 11 quotations (cf. Figure 1).

When considering the total number of literal quotations in the *Physica Generalis*, we get another impression: In this connection too, Boscovich plays an eminent important role, as Biwald quotes him 23 times. But the second place is held by Musschenbroek with 20 quotations. Newton only follows after Lacaille (6 quotations) with 5 quotations and after Kepler (4 quotations) the next Newton commentary –Maclaurin– follows with 3 quotations (cf. Figure 2).

---

[17] Publications characterized by a mere astronomical focus (such as Lalande's works) are excluded from the considerations in this connection because of their specific target.

[18] For a more extensive analysis of this question (including further bibliographical references) cf. Cornelia FAUSTMANN, Zur Bedeutung des Lateinischen als Wissenschaftssprache im 18. Jahrhundert. Ein Beitrag anhand der Physica Generalis des Leopold Gottlieb Biwald, S. J., in: *Sprachen der Wissenschaften 1600-1850* (ed. by D. Ulbrich), 2010 (Themenheft Jahrbuch für Europäische Wissenschaftskultur) [forthcoming].

[19] *Theoria Philosophiae Naturalis redacta ad unicam legem virium in natura existentium, auctore P. Rogerio Josepho Boscovich Societatis Jesu, nunc ab ipso perpolita, et aucta, Ac a plurimis praecedentium editionum mendis expurgata*. Editio Veneta Prima ipso auctore praesente, et corrigente. Venetiis, MDCCLXIII. Ex Typographia Remondiniana. Superiorum permissu, ac privilegio.

[20] If there are certain reasons for the predominance of non-Jesuit commentaries on Newton quoted by Biwald as sources for his explications of Newtonian physics, cannot be answered in this connection.

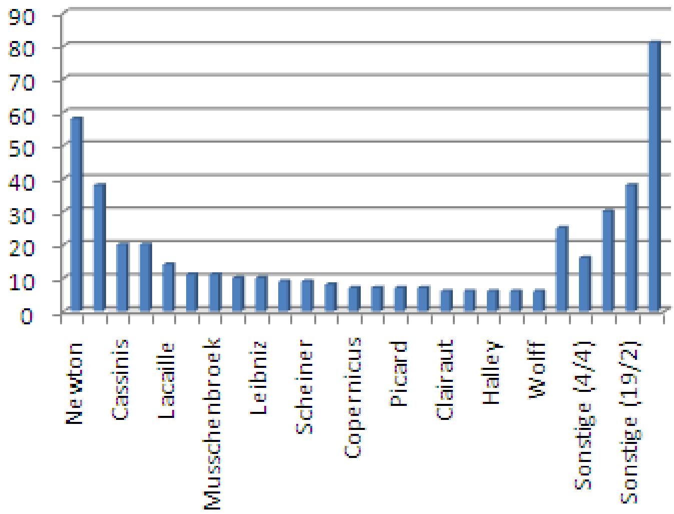

Fig. 1: Number of scientists mentioned in Biwald's *Physica Generalis*.[21]

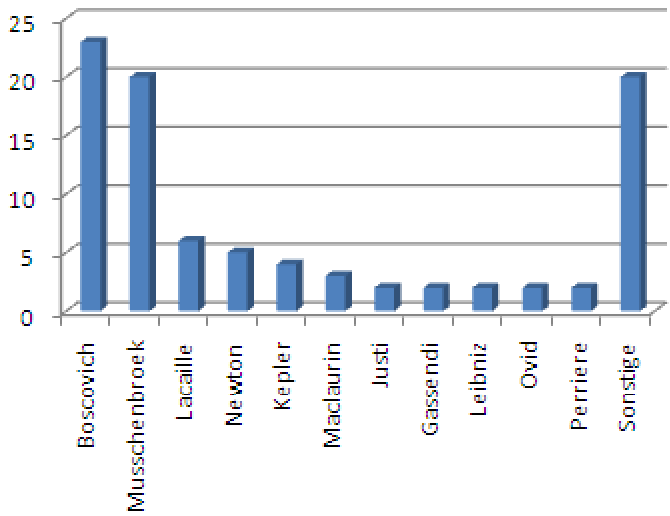

Fig. 2: Number of literally quoted scientists/authors in the *Physica Generalis*.[22]

The number of literal quotations of different scientists respectively authors can only be considered an indicator for Biwald's very near orientation on certain sources, therefore the whole text of the *Physica Generalis* has to be analyzed in order to approve or refute the impression received by the quotations. As far as the importance of Newton's *Principia* respectively commentaries on Newton as sources for Biwald is concerned, the results of the examination of the quotations in the *Physica Generalis* can be verified for the whole textbook – so Biwald uses commentaries on Newton, above all the publication written by Musschenbroek, more likely than Newton's *Principia* themselves.[23] And yet the importance of Newton himself as the most prominent scientist besides Boscovich in the *Physica Generalis* is clearly given because of the numerous remarks about him throughout Biwald's textbook.

[21] FAUSTMANN, *Physik des 18. Jahrhunderts im Spiegel der Quellen* (cf. n. 13), 237.

[22] FAUSTMANN, *Physik des 18. Jahrhunderts im Spiegel der Quellen* (cf. n. 13), 237.

[23] FAUSTMANN, *Physik des 18. Jahrhunderts im Spiegel der Quellen* (cf. n. 13), 237.

However, additional other sources have to be taken into account when analyzing intertextual approaches of this kind in the *Physica Generalis* – namely physics textbooks, which Biwald does hardly ever or even never quote in his compendium. When considering the wording of Newton's today very prominent axioms of motion as example and comparing their wording in the edition of the *Principia* used by Biwald and the wording in the *Physica Generalis*, there are apparent differences.[24] However, if the wording of Newton's axioms in Karl Scherffer's physics textbook *Institutiones Physicae* is taken into account, it becomes clear that Biwald copied Scherffer's wording – because it is exactly the same as in the *Physica Generalis*.[25] So this and many other examples show that Biwald's reception of Newton is carried out via certain physics textbooks and commentaries of Newton to a large extent, which thoroughly is an adequate method for a physics textbook of the 18th century like Biwald's *Physica Generalis*. However, Biwald undoubtedly was expert enough in Newtonian Physics – this aspect is shown in the author's selection and combination of different relevant source texts in order to create very well understandable explications as well as in deviations from source texts and totally independently written passages, which also is a quality criterion of the *Physica Generalis*.[26]

Conclusion

Considered as a whole, it is clear that Biwald could stick to a lot of 18th century sources. Within the scope of the analyses above it became manifest that commentaries on Newton's *Principia* and Newtonian textbooks are more important as sources for the *Physica Generalis* than the *Principia*. Biwald does not focus on Jesuit sources when explaining Newtonian physics, so there were no confessional boundaries in this connection in the 18th century. Additionally, the geographical distribution of the texts used by Biwald shows a very well working Jesuit network at that time, which is also illustrated by the fact that the reception of the sources happened proportionally quickly. As far as Biwald's specific achievements regarding intertextuality are concerned, the adequate selection of sources, the combination respectively compilation of different texts in order to make the descriptions as understandable as possible, and deviations from the methods of explications of the sources as well as independently written passages are the most important aspects. Additionally, Biwald's very clear style and an especially for his target audience useful structure of the material have to be seen as criteria for the success of Biwald's compendium at its time in whole Europe.

HALLERSTEIN AND GRUBER'S SCIENTIFIC HERITAGE

Stanislav Joze JUZNIC
Research and Development Department, Fara, Municipality of Kostel, SLOVENIA, and Oklahoma University, USA
juznic@hotmail.com; stanislav.juznic-1@ou.edu

Abstract

Augustin Hallerstein's (1703 Ljubljana; † 1774 Beijing) role in the Beijing Jesuits' electrical and vacuum research was not that clear as his publications in astronomic, cartographic, Aurora Borealis, or China demographic research. The Jesuits were not always useful in all aspects but they were also not evil or mean all the time. The same goes for Hallerstein's younger Slovenian compatriot Gabrijel Gruber's (* 1740; † 1805) Jesuits in Russia who brought the western education, technology, and science to Petersburg. The Jesuits tried to sell their superior scientific and technological know-how to their hosts as the keys unlocking hosts' hart and most of all their souls. They especially favored the souls of domestic high society including the Russian or Chinese Emperor because the Jesuits hoped to repeat the Roman Emperor Constantine's example. General Gruber eventually nearly won Tsar Paul's soul for the Catholics, but the Chinese Jesuits were never that close. Hallerstein happened to be among the first to figure out that all tools will never be enough to conquer the Tsar's soul for Christianity, and therefore somewhat disappointed Hallerstein devoted most of his strength to the science on both opposite ends of Euro-Asia with numerous European Publications. The science Hallerstein offered to the Chinese was not always up-to-date because the Lisbon-Canton ship connection returned his mail only once in two years, which is far the from modern internet capabilities. Hallerstein was extremely proud of his observatory, and didn't hide it from the visitors. Even the military oriented experiments, which would be today considered as top-secret, were freely published in European scientific journals before French Revolution, and there was no reason for the Jesuits to hide the European knowledge from the Chinese. With the Chinese Jesuits still on board, the Chinese technological gap would not broaden so deep as it did after Hallerstein's death. With Gruber's Jesuits still on board, the Russian educational system could have produced even more pro-Western literati with* Decabrists' *souls to fulfill Peter the Great's goal of Westernization.*

Introduction

The best known Slovenian Jesuits, Augustin Hallerstein and Gabrijel Gruber, accomplished their scientific-political success in the greatest Eastern metropolis, Beijing and Saint Petersburg. Edo-Tokyo was beyond their reach in those times. They followed the Mattheo Ricci's plan: amaze the domestic nobles with superior Western science&technology to win their souls for Catholicism. The science&technology was their tool and the political-theological success their goal. Hallerstein soon figured out that his goal, namely the conversion of the Emperor, is beyond any real expectations. He decided to cultivate just the first part of the plan, the sciences. His younger compatriot, Gruber, had stronger political position in Saint Petersburg and never abandoned the second part of the plan, even if his Tsar Paul the 1st was killed just in the time Tsar was about to became the Catholic. While the early Ljubljana Gruber's work was dedicated to education&technology, his later Russian life was predominantly occupied with politics including the attempts to incorporate Hallerstein's Chinese successors into new Jesuit Society. Hallerstein never reached that second part of his projected achievements because of the unfavorable political climate in Beijing Court, and researched in sciences with the most of his strength. Therefore the history of science&technology values Hallerstein's work higher although the young engineer Gruber expertly dug water canals or designed buildings in engineering manner highly above Hallerstein's range. On the other hand Gruber published just some magnetic measurements besides his optical and hydro-mechanical work, while pure science dominated all Hallerstein's life. Hallerstein and Gruber expressed extraordinary mathematical-scientific, linguistic, and diplomatic-political abilities. While Beijing circumstances enabled Hallerstein to fulfill only the first group of his talents, the Tsar Paul 1st politics favored the last group of Gruber's capabilities.

Hallerstein's Electricity

Hallerstein was able to study Pascal,[1] Schott,[2] Newton, Lana Terzi, Musschenbroek,[3] or Laurentio Gobart's (* 1656 Liége; † 1750 Liége) 1716 and 1746 vacuum experiments in his uncle Franc Mihael Baron Erberg's (* 1679; † 1760) library or in Franciscan Ljubljana Library. He continued to use the same books in the Beijing Jesuit libraries. The magnetism seems to be Hallerstein's first love. He measured the declinations of the magnetic needle while sailing to China. Later, he made similar observations in Beijing,[4] where Nicola Cabeo's (* 1586; † 1650) *Philosophia magnetica*[5] and Ferdinand Verbiest's magnetic theory still prevailed over the more modern William Gilbert's followers,[6] although already Schreck's collaborator Nicolas Trigaut (* 1577; † 1628) acquired Gilbert's *De magnete* (1600) for his Macao and after 1623 Beijing Library.[7] It is also possible to determine the books, which other Far East missionaries used, but no bookplate bears Hallerstein's name[8] because he preferred to use the bookplate of his Beijing College. Modern catalogues probably do not show all Beijing missionary books because some of them were probably lost or borrowed.[9] Before he put anchor in Canton in September 1738, Hallerstein studied the electricity research of Stephen Gray (1729), Charles François de Cisternay Du Fay (1732), and Du Fay's student Abbé Jean Antoine Nollet.

In 1750, the Jesuits of Hallerstein's Portuguese college of St. Joseph in Beijing received the electrical machine and the instrument for the observation of the eclipses. Sanchez[10] provided the instruments from his friends in London and

Holland. The bishop of Beijing after 1740, named de Souza,[11] saw over the shipping.[12] No document mentioned the nature of Hallerstein's electrical machine. It could be electrostatic frictional device or Musschenbroek's Leyden jar invented in November 1745 and announced in January 1746. The former Leyden student, Sanchez, knew Musschenbroek's Leyden jar experiments. At the same time, Peter Collinson[13] of the Royal Society of London shipped the Leyden jar to Benjamin Franklin across the Atlantic. Sanchez corresponded with Collinson and sent him the rhubarb plant obtained from the Beijing Jesuits.[14] On October 25, 1753 Collinson sent the mimosa flower to the Hallerstein's friend, glassmaker and Emperor's Beijing gardener Pierre Noël Chéron d'Incarville (* August 21, 1706; † June 12, 1757).[15] On November 2, 1747 d'Incarville reported to Parisian Bernard de Jussieu (* 1699 Lyon; † 1777 Paris) how Hallerstein gave him Johann Schreck's herbarium *Plinius Indicus* with the plants minerals and animals picked up in nature and collected in Hernandez' Mexican way. J. Gruber described Schreck's herbarium to Kircher. Schreck was Galileo's former collaborator in the Academy *dei Lincei*, and he coauthored Federico Cesi's (* 1585; † 1630) Roman publication of Hernandez' notes on Mexico plants *Thesaurus Mexicanus* in 1651. Under the Ming Emperor Schreck was able to travel around in search for plants or minerals. Kepler published Schreck's letter in *Ad Vitellionem* (1604) which Hallerstein inherited from the missionary Alexandre de Rhodes (* 1591; † 1660 Ispahan in Persia).[16] Hallerstein allowed d'Incarville to copy the Schreck's herbarium for his and Jussieu's use, so there were just three exemplars of the unpublished item, which Kögler have to Hallerstein before he died. D'Incarville sent the copy to Jussieu in three letters dated 1747, 1748, 1751 and to Claude-Joseph Geffroy (* 1685 Paris; † 1752 Paris), who died before finishing the comparative studies.[17] In February 1746, the Royal Society secretary Cromwell Mortimer asked the Chinese Jesuits to mail him the butterflies and their larvae. Hallerstein hired d'Incarville to do the job because he was the most leaned botanist among the monks as he reported in his letter on September 18, 1750.[18]

As the leading scientist among the Beijing Jesuits, Hallerstein experimented with the electricity. His collaborator from French college Amiot was especially interested. French college of Beijing probably had no electrical instruments. Therefore, Amiot had to borrow Hallerstein's equipment from the nearby Portuguese college. Hallerstein had much better equipment according to his friend, the French Beijing Jesuit Gaubil.[19] At that time, Amiot, Hallerstein, and Gogeisl cooperated on the measurement of the height of the star Gamma in Andromeda to match the order of Pezenas[20] and two other Jesuits, who made similar measurement in Marseilles.[21]

The Beijing Jesuit electrophorus experiment under Hallerstein's supervision, described in Jesuits' letter mailed to Petersburg, was a corporate Jesuit work highly praised in the Petersburg academic circles. In 1779 letter addressed to the Emperor's gardener named after d'Incarville's death, Peter Cibot, the Petersburg academicians expected the continuation of Beijing Jesuits' research in electricity[22] which eventual did not appear after 1755. In 1755, the Beijing Jesuits electrified a thin glass plate by friction and put it on the glass coverage of the magnetic needle. They probably used the "electric machine" which Hallerstein received in 1750. The needle suddenly raised and adhered to the inner side of the glass wall for few hours. Later it returned to its normal position. When the Jesuits removed the previously electrified glass plate, the needle rose again and remained in touch with the glass cover. When they returned the plate, the needle fell down again, and the Jesuits repeated the experiment many times.[23]

On January 12, 1755, Gaubil received the undated letter of Richman[24] and Kratzenstein's letter dated April 12, 1753 addressed to the Jesuits of Beijing. Gaubil wrote back to both Petersburg academicians on April 30, 1755, and mentioned Amiot's experiments "that should make you happy." Gaubil complained that the Chinese were not very interested in electrical experiments[25] compared to the European and American euphoria of that time soon after the Musschenbroek's invention of Leyden jar. Even the medical use of electricity was not Chinese match, although Kangxi (康熙帝, ruled 1662-1722) during his illness highly praised European anatomical knowledge[26] of Harvey and Vesalius[27] borrowed via the French Beijing Jesuits Parrenin (* 1665; † 1741) and Joachim Bouvet (* 1656; † 1730).

On November 25, 1753, the Russian Academy of Science proposed the award for the best explanation of the true causes of electricity including their theory, with a deadline June 1, 1755.[28] They were interested in chemical and physical aspects.[29] For September 6, 1751 the Empress Elisabeth and the Academy president Count Kiril Grigorjevič Razumovskii (* 1728; † 1803) proposed a Lunar theory competition, and on November 26, 1753 dissolution of silver in *aqua fortis*. For the year 1756, they offered award for corpuscular theory, and for 1757 competition they put into limelight the diurnal planetary motion. On September 6, 1755, the Empress announced the awards without mentioning Beijing contribution, which was probably the part of competition. The first award (*praemio coronato*) went to Leonhard Euler's son Johan Albert Euler for his *Disquisitio de causa physica electricitatis*. Other two elected researchers were professor in Pisa University Paul Frisi (* 1727; † 1784) from Paul's clerical order[30] who discussed the causes of electricity, and Lalande's Jesuit teacher and director of Lyon observatory after 1740, Laurent Béraud (* 1703 Lyon; † 1777), who put forward his theory for the award of Petersburg academy. Euler tried to calculate the speed of electricity from the elasticity of ether, and experimented with the conductivity of the vacuum above quicksilver in barometer. Euler used Mussenbroek and Kleist's Leyden jar,[31] and discussed Martin Frobenius Lederemüller's (* 1719; † 1769) experiments with the spirit of wine. Frisi developed Kratzenstein's experiments[32] to please the academicians, and used Mairan Parisian theory, Bernoulli's vibrations, Bose, Beccaria, and Jean T. F. Jallabert's (* 1712 Geneva; † 1768 Geneva) experiments.[33] In the last, 5th, experiment Frisi repeated Franklin's glass jar conclusions, and moved to the theory of John Théophile Désaguliers (* 1683; † 1744). He also relied on the ideas of Monnier, Franklin's antagonist Nollet, Martin Frobenius Lederemüller, and Winkler. Frisi added some simple calculations with corresponding figures attached to the end of the book. Béraud used L. Euler theory of force for Boyle and Hale's molecular theory and heavily relied on his compatriot Nollet's experiments, while briefly mentioning Franklin.[34]

The copy of academic publication of electricity research of Euler, Frisi, and Béraud (1757) passed to the tertiary Franciscan Alexander de Gouvea (* 1731 Evora in Portugal; † 1808 Beijing), the appointed Beijing Bishop in 1782, who used his stamp as a bookplate.[35] In August 1755, Gaubil sent to Razumovskii two Amiot's packets and other presents.[36] Gaubil knew that Richman and Kratzenstein widely published on electricity, but he was not aware of Richman's accident on July 26/August 3, 1753. Soon afterwards, on August 13, 1753, Kratzenstein left the academy of Petersburg and became the professor of medicine and physics in the University of Copenhagen.[37]

Zeiher[38] replaced Kratzenstein in 1756 and reported to Gaubil how Richman's unfortunate death[39] shocked the scientists worldwide. A.Hallerstein's first cousin Baron Erberg bought Kratzenstein's research of vapors republished in Trnava in 1763. After working in Berlin for a short time, Aepinus inherited Richter's membership in the Petersburg academy. Aepinus was born in Rostock in Prussia where he completed his studies and taught. He collaborated with his Swedish student Johann Karl Wilcke (* 1732; † 1796) on the early type of condenser which Volta later developed into electrophorus in

the gymnasium of Como in 1775 where he taught, before he got a chair in Pavia University. On May 10, 1757,[40] Aepinus arrived to Petersburg and remained professor of physics in the academy until 1798.

The new professor of physics Aepinus[41] immediately analyzed the Beijing experiments to please the Russian authorities. Just few months later he reported on the Beijing experiments to the Petersburg academy[42] and described his research on March 9, 1758. Aepinus explained the Jesuits' Beijing experiment with the small conductivity of glass, which allowed the induced charge on the compass' glass coverage, slow movement of the charge into the attached compass' needle during the experiment, and equally slow returning of the charge after the induced charge removal. Aepinus successfully repeated Beijing experiment and figured twelve similar experiments of his own. He believed that Beijing experiment fully confirmed Franklin's theory.[43] It was certainly also a political question in the middle of the Franklin and Count Buffon's quarrels against Nollet and d'Alembert in France. The Beijing Jesuits' support of Franklin's ideas mirrored the Jesuit physicist Rudjer Boskovic's close friendship with Franklin. Hallerstein certainly knew Boskovic's work pretty well. Boskovic was few years his younger, but he used Boskovic's work, and A.Hallerstein's brother Vajkard Hallerstein was the confessor of Emperors brother in Brussels where Boskovic frequently visited his friend, the Habsburg Netherlands' Governor Count Janez Karl Filip Kobencl (* 1712 Ljubljana; † January 27, 1770 Brussels) from Hallerstein's native Ljubljana. We could consider Aepinus' mathematical theory of electricity as a part of the mainstream to which Beijing Jesuits' electricity research also belonged. Hallerstein and his Beijing collaborators could have read Franklin's letters to the wealthy English Quaker Collinson about electricity of Leyden jar published in English (1751) or French (1752), or Beccaria's Latin compilation (1751) before they prepared their electrical experiments, which were drastically different from Franklin's achievements. Sanchez and Collinson provided the necessary equipment for both research groups, Franklin's group in America and Jesuits' college in Beijing. Both target groups proved extremely successful, and returned the gift with unexpected extraordinary new discoveries. Sanchez and Collinson both collaborated with the London Royal Society, but Franklin did not cooperate with Beijing Jesuits although the leading European Jesuit Boskovic became his close friend. Both target groups in America and China communicated just through the good old Europe. Franklin himself probably did not bother to repeat Beijing Jesuit's experiment because he switched to diplomatic-political waters son after he gained his fame in the field of electricity. It is also not widely known if the Beijing Jesuits repeated Franklin's experiments, or even introduced the Lightning Rods into China, but technically speaking their experiments brought even more fruit through Volta's research even if they received far less fame compared to the clever diplomat Franklin. Hallerstein or other Jesuits in China did not have any Franklin, Beccaria, or Boskovic followers' books[44] at least they are not preserved.

Aepinus discussed the electrical and magnetic forces for the Academy and dedicated his research to the Empress on September 7, 1758. He used the experiments with Leyden jar to explain the analogy between electricity and magnetism but he did not mention the Beijing report although he used the Jesuits' Beijing data.

In autumn 1758, Aepinus developed his mathematical theory of the electric and magnetic effects. On June 4, 1759, Aepinus presented his book to the academy. In late November,[45] he dedicated it to Razumovskii. Aepinus used his favorite Franklin's theory of one fluid without mentioning the Beijing experiments.[46] But Aepinus' explanation did not please everyone. He had to excuse from his readers because he used to sophisticated mathematic in the field of electricity which was

[44] Hallerstein used Paris academic publications, one of them with d'Incarville's article published in 1755 (Verhaeren, 1969, 3-4). Hallerstein had Musschenbroek's textbook *Elementa Physicae* in three editions with the older ones bearing Sousa-Sanchez and Gouvea bookplates (Verhaeren, 1969, 669-670). He used Boyle's works on vacuum techniques (Verhaeren, 1969, 312, 315), Hooke's *Micrographia* in the first English 1665 edition with the bookplate of China vice-provincial appointed in 1727, Joao de Saà (* 1672 Sambujat in Portugal; † 1731 Macao) (*Aplicado à Resid^{a} de Chinkiam por ordent Publicada pello P. VProv^{ai} Joao de Saà* (Verhaeren, 1969, 1198; Pfister, 1932, 484). Saà also had Gemma Frisius *De Principi Astronomiae&Cosmographiae* (1553. Antverpiae: Ioannis Steesii (Verhaeren, 1969, 487), and his successor vice-provincial, superior, and Emperor's mathematician Karl de Rezende (* 1664 Lisbon; † 1746 Beijing) wrote his bookplate *Comprado p^{a} Chim tim fu pello P. Carlos de Rezende em 1734* in Carlo Fontana's (* 1634; † 1714) *Utilissimo trattato dell' acque correnti* (1696. Roma: Gio. Francesco Buagni) (Pfister, 1932, 483-484; Verhaeren, 1969, 956 (No. 3271)). The Beijing missionaries also had Newton's books including his English Theology (Verhaeren, 1969, 1099-1200), the Viennese Marinoni (Verhaeren, 1969, 637), Hallerstein's favorite astronomers, the Bolognese Manfredi and Zanotti's four copies of 1750 edition, two of them with bookplates (*Jam ab aliquot annis, anni 1726 tomum lipsiensem acceperamus. Hunc itaque R^{do} P^{i} Andre. Pereyra D D. Servus in X^{o} humillium. C Gaubil SJ.* and *Dono De Lisle* (Verhaeren, 1969, 632-633)), Zanotti's ephemerides (1750) (Verhaeren, 1969, 912), and Johann Leonhard Rost (* 1688; † 1727) *Der Aufrichtige Astronomus* (Nurnberg 1727) (Verhaeren, 1969, 1151).

[45] Novik, 1999, 12-13.

[46] Aepinus, 1979, 130-131.

traditionally (ab)used by philosophers or experimentalists without any love for higher mathematics. Symmer[47] conducted two sets of experiments similar to the Beijing ones which he apparently never heard of. Symmer presented his results to the Royal Society of London between February 1 and December 20, 1759. He concluded with an essay about two distinct powers in electricity[48] which pleased Franklin's opponents.

Cigna[49] was the first to comment on Aepinus' analysis of Jesuits' experiment,[50] and Cigna's uncle Beccaria[51] was interested in Beijing Jesuits' results too. In 1747, Beccaria became professor of experimental physics at the University of Turin. Although he was member of different religious order called Scolopi or Piaristen, he was a close Boskovic's friend and an admirer of Franklin's achievements. In 1767, he added a previously unknown similar effect to the Beijing Jesuits' experiment. He charged the coated glass plates. He removed the coating from the negative plate and put other neutral uncoated glass plate nearby. He coated uncharged plate and used the conductor to connect its coating with the coating of charged plate. The plates touched and leaned on each other with the whole area. If he separated the plates after they were in touch for some time but before the fusion, the charged plate got the positive charge on both sides and the uncharged plate got the negative charge on both sides. If he separated the plates after the fusion, the charged plate became negative on both sides, and the uncharged became positively charged on both sides. If after the fusion he separated and again joined the plates, the small circled paper under the uncharged plate fused to it after each separation and got repelled after each touch. Beccaria was able to repeat the experiment for as many as 500 times after the single charging of the plate.[52] It was the great advancement compared to the Leyden jar experiment where the recharge of the jar was necessary after each experiment. The era of the steady electricity current was on board thanks to the Beijing experiments.

In 1769, Beccaria reprinted the Beijing report, mentioned Aepinus mathematical explanation as incomplete, and put forward the explanation of his own. He offered the idea of the special "*electricitas vindex*".[53] Beccaria was an experienced researcher, but even he had his shortcomings. Alessandro Volta worked in Como and later in the Habsburg University of Pavia where the Jesuit Boskovic and former Carniolan naturalist Anton Scopoli used to lecture before him. Volta was not satisfied with Beccaria's explanation and the urgent search for other possible explanations led Volta to the invention of electrophorus several years later described in a letter to Priestley dated June 10, 1775.[54] Volta was a Habsburg North Italian employee and his electrophorus was quickly introduced in the Habsburg Monarchy, especially by the Empress Maria Therese's personal physician Dutch Jan Ingenhousz (Ingen Housz, * 1730 Breda in Southern part of the Dutch Republics; † September 6, 1799 Wiltshire) who published his own contributions. The German Molitor's Viennese translation of Ingenhousz's work was published in 1781, just before Ingenhousz returned to England. It was already too late for Hallerstein to learn more about Volta and Ingenhousz from his Viennese collaborators, because Hallerstein passed away in 1774.

Gruber's Technology for Politics

As a young Jesuit Gabriel Gruber wished to follow Hallerstein's example in the China Jesuit missions, but he was never accepted. Authorities needed his mathematical, technical, or diplomatic abilities in Europe. The Viennese born professor of Slovene origin Gruber made successful engineering career in Ljubljana, White Russian Polotsk, and Petersburg. As director of the first of the two Habsburg Monarchy navigational Divisions he worked most of all on Mur River between Graz and Radgona, Drau River around Ptuj, Sava River, and Hungarian-Rumanian rivers. Gruber and his staff built two models of the "machine ship" for upstream navigation in 1779/1780, and successfully trued them on Mur River. Gruber's model of "machine ship" was comparable with the contemporary achievements in France, England, and even in the recently established USA where the Fulton's steamboats soon brought the success.

Gruber build the Ljubljana canal, and for many decades designed canal connecting the Adriatic with Black Sea. He published new data about that *Argonaut* road in Prague in 1802 when he was already a Jesuit General. As pioneer of the karst research Gruber examined underground water connections allover today Slovenian Karst to prepare the Ljubljana Canal Design. As physicist he researched the *fata morgana* optical illusions above the water of the Cerknica Lake. With the help of his brother Tobias Gruber, the president of Bohemian Scientific Society, Gabrijel Gruber accomplished pioneering *fata morgana* laboratory experiments.

54 Aepinus, 1979, 131; Volta, 1816, IV, 108. Joseph Priestley (* March 13, 1733 Fieldhead; † February 6, 1804 Northumberland).

In Polotsk Gruber researched connections between earthquakes and terrestrial magnetism, and published his experimental measurements in Jena. He combined his scientific, artistic and engineering practice with exceptionally successful political and diplomatic career eventually becoming Jesuit General and influential unofficial political advisor of the Tsar Paul I. Gruber connected east and west technologies. He designed architectural novelties as the first professor of architecture in Russia. Gruber used his technological, artistic, and scientific skills to navigate between Scylla and Charybdis of Napoleonic politics eventually preparing the Conclave for Pius VII election, or even the Tsar Paul's association with Napoleonic forces. Gruber was the most successful follower of the doctrine *for the greater glory of God* and used his technical-scientific knowledge for that purpose. The 18th century Jesuits lived as priests and scientists in the way never achieved before or after, although few Franciscans and other friars certainly were their match. Because of the rite controversy Chinese Jesuits with Hallerstein as their leader abandoned the idea of converting the Emperor. The Hallerstein's Jesuits predecessors in Beijing believed in the success, but Hallerstein himself already had considerable doubts expressed in several letters mailed to his brother in Brussels. The extra time gained enabled Hallerstein's full-time scientific research.

The Jesuit idea of converting the ruler as a prelude for his country's Catholic conversion was rather old Constantine's[55] example. We claim that Hallerstein abandoned the politics for the attempted mass conversion from the top and rather tried to win Chinese for the European Science. The Jesuits always used knowledge as propaganda showing that Catholics with better science-technology should also provide a better faith and church. Hallerstein published as much as possible of his Chinese measurements in Centers like London, Paris,[56] Lisbon, Petersburg, or Vienna. He eventually took the trouble to publish his best scientific results in Europe as far the most successful of all Jesuit Beijing missionaries considering his European publications.

The idea of conversion from the top downwards was not buried at all with the Ljubljana Jesuit Hallerstein's soft politics in Beijing. His younger countryman Jesuit General Gruber was the most successful follower of the "top to bottom" conversion idea of all times. Gruber in Russia did not accept Hallerstein's kind of defensive political role and nearly made the Emperor Paul I his Emperor Constantine.

Russian court just occasionally took some interests for the Jesuits' connections with the Far East which could assist Russian invasion of the East. The Tsarina Catharina the Great used the exceptional Gruber's diplomatic abilities immediately after Gruber's arrival. In 1785 the White Russian gubernator Passek passed to the Russian Jesuits the order of the court asking them to send two capable Jesuits to the Russian capital. The Jesuits named Manswet Skokowski (Mansuetus, * February 20, 1751 White Russia; SJ August 13, 1770 Nieświež; † February 8, 1798 Mscislaw) and Gruber for the secret mission, immediately after Gruber's arrival. Gruber was asked to obstruct the English influence in China which began to grow after the year 1785 and especially after the Chinese Emperor talked to the English representative, Lord James McCartney, in 1792.[57] The task was not easy and Gruber got things done very slowly. He and his helper returned to Polock to wait for the new invitation from Petersburg court.

During his June 1799 visit of Petersburg Academy Gruber wrote a French letter to the Tsar,[58] asking him again to write to the Pope for official recognition of Gruber's Jesuits. In the second paragraph Gruber remembered the Papal spoken support of the legacy of Jesuits in (White) Russia. In the third paragraph he limited the legacy just on Russia without mentioning the world-wide expansion of the former Jesuits. Gruber underlined the success of Jesuits' juvenile educational program in newly conquered Russian lands with no note on the Catholics of former Polish territories. In the fourth paragraph Gruber put in the limelight the diplomatic advantages of the broad legitimism of Jesuits which could enable the official support if the former Jesuits in Beijing. The Tsar certainly had a lot of diplomatic or trade interest in China, and Gruber put them forward ingeniously. After the suppression the status of the Jesuits in China was certainly unstable and Gruber therefore asked the Petersburg Court to submit the letter for the Pope about the legitimization of Jesuits. He wrote about China »*where it is necessary for the success of all the diplomacy that I travel and (stop) the rumors against the Jesuits who cannot work in (those) areas without the written permission*«. In his 5th paragraph Gruber stated that the Duke of Parma and many other rulers support his plans. Many peculiarities of Gruber's courting the Chinese Jesuits were destroyed in fire which caused Gruber's death in 1805.[59]

The Tsar Paul suggested to Gruber that he should send two Jesuits for China. That was one of the rare ideas which Paul inherited from his mother (1792), and even his son Alexander liked it. In May 1799 Gruber and Skokowski were invited

to Carskoje selo without any definitive success.[60] On January 16, 1800 Gruber and Kamienski left Polock again to meet the Tsar, but they had a lot of problems.[61]

Gruber got the official patronage and even free entrances into the rooms of the Russian Tsar Paul I,[62] who usually accepted him with the Jesuit's slogan "*Ad majorem dei gloriam*!"[63] The Tsar even publicly declared himself as "the Catholic in hart",[64] which was certainly a strange position for the nominal leader of the Russian Orthodox. On August 11, 1800 in Gachin the Tsar suggested to the Turkish Authorities and to the Swedish king that they should recognize Gruber's Jesuits in their states. On the same day the Tsar finally mailed a letter to the Pope asking him to legitimize the Jesuits.[65] Paul's days were nearly over but his letter finally gave Gruber all he wanted. However, on the March 11/23, 1801 evening Paul was murdered in his bedroom of St. Michael palace in Petersburg.

Once in the saddle, Gruber made huge efforts to re-establish the Jesuit hierarchy in China. In that way he continued the work of his compatriot Hallerstein a quarter of century after Hallerstein's death. Gruber certainly followed Hallerstein's ideas and had considerable success in courting Hallerstein's Chinese successors. Gruber certainly knew how to select the useful helpers in China. His main connection in Beijing was the former Jesuit Mandarin, Louis de Poirot.[66] On March 20, 1770 Poirot and Luigi Cipolla[67] boarded the Portuguese ship, and on October 20, 1770 they put their anchor in Canton. Poirot arrived to Beijing on August 14, 1771. The painter Poirot got his Mandarin after his excellent translations during the McCartney's visit, and he grew famous for his translation of the Bible in Chinese and Manchu. In September 1802 he asked to join Gruber's Russian Jesuits.[68] Cipolla finished his medical studies because the Chinese court of those times was short for physicians and painters. Cipolla asked for a permission to change his Beijing French Mission with the Portuguese one because he wished to work in Hallerstein's Astronomical Bureau. After the suppression of the Jesuits Cipolla became the propagator in Beijing in 1776. He asked to join Gruber's Jesuits (1805) after Gruber added to his letter of invitation the most suggestive advice of Cipolla's juvenile friend, Eduard Desperamus.[69] Gruber knew how to invite his former Jesuit brothers to rebuild the Jesuit Society.

Among others, the Slovakian-Viennese astronomer Maximilian Hell and the Bishop of Nanking Laimbeckhoven asked to join Gruber's Jesuits.[70] In that way Gruber used the high politics to attract the Viennese editor of Hallerstein's scientific works, Hell. In the same time he talked over Hallerstein's best friend, Laimbeckhoven.

The Tsar Alexander was even more willing to support the Jesuit work on the Far East compared with his farther or grandmother. Therefore Alexander and Gruber easily found their mutual course for the Jesuit work in Siberia near Chinese border. In 1802 the new interior minister, the Prince Viktor Pavlovic Kocubej (Kocubei, * 1768; † 1834) supported Jesuits' missionary work.[71]

Gruber learned about the Siberian and American circumstances already in Ljubljana after reading Ignaz Born's[72] expert Natural History freemason Journal *Physikalische Arbeiten der einträchtigen Freunde in Wien* for the years 1783, 1784, and 1785. In March 1802, the Tsar Alexander suggested that three Gruber's Jesuits should join the Chinese deputy of Russian Embassy. One of them should be Pole, other German, and an Italian. In that way Alexander fulfilled a decade older wish of his grandmother Catharine. Gruber did not allow to be asked twice and in September 1802 he selected the Polish Father-mathematician Norbert Korsak (Corsak),[73] Italian mathematician Giovanni Grassi, and German lay-brother Johann Sturmer. Gruber gave them a letter for the Chinese together with the Russian Imperial addenda. In 1805 they sailed across

Denmark to Portugal and stayed for a while in Coimbra. But the Cardinal Consalvi[74] and the Roman congregation for the propagation of Faith (*Propaganda Fide*) stopped the procedure.[75] The Russian Tsar finally forbade the Chinese journey of the Jesuits. Korsak went to England, Grassi became the 5th president of the Georgetown College (1812-1817),[76] and Sturmer left the Jesuit Society in Petersburg. Gruber died in between and did not witness how his carefully planned renewal of the Beijing Jesuit Mission failed.[77]

A year after Gruber's death on June 29, 1806 the Tsar allowed the Jesuits to enter Siberia, although Gruber's antagonist Stanislav Jan Siestrzencewicz-Bohusz (Sestrencevič, * September 3, 1731; † December 1, 1826) preferred the Dominicans. Two Jesuits lived in East-Siberian Irkutsk, and other two in West Siberia. In December 1811 two Jesuit Fathers left Polock for Irkutsk and arrived there on April 1, 1812. The huge city and the landscape pleased them in spite of the expensiveness. Later one of the fathers went to West-Siberian Tomsk. The Siberian mission was a part of the Archbishopric of Mogilev, and Siberians called around thousand Catholics in Irkutsk with their ancient name *Poles*. The connection between the faith and nationality was similar as among the Serbians and Croatians but it was abandoned earlier because of the quick separation between Russian and Polish languages with much more numerous speakers. The similarity between being Catholic and being Pole was lost in European part of Russia already in Gruber's time.[78]

The leader of the Russian Uniats, the Archbishop Krassowski, lived in Polock as did the majority of Russian Jesuits. He soon began to complain because the Jesuits baptized the children of the Uniats in Siberia. The Russians planned to make their way through Siberia to China, but they did not allow the Jesuits to cross the Chinese border. The only Jesuits allowed to do so were the Chinese Emperor's deputies during the signing of the peace in Nerchinsk on August 27, 1689. More than a century later the situation was completely reversed because the Russian Jesuits were allowed to visit Nerchinsk east of Irkutsk, but they were not allowed to enter China which they desired urgently.

After the Jesuits had to live Russia in 1820, the Siberian Jesuits went to Galicia because Chinese or Russian did not need their mediation to settle their mutual quarrels on the border. The Jesuits became the intolerable elements for both sides, and Russians tried to replace them with some more obedient Catholic Order.[79] As the result, Moscow, Saratov, South-Russia, Siberia, Riga, and other Russian missions did not prosper in a way which Gruber planned and wished.

Gruber was the most successful follower of the Ricci's method of combining the successful Western science&technology with the Catholic propaganda. Gruber decisively influenced Bishop Carroll's development of the catholic hierarchy and Jesuits Schools in USA. The USA situation was different from Europe or China in many aspects because the new world settlers' cultural-scientific level was comparatively low in Gruber's time. In spite of the Jesuit Boskovic's friendly relations with the American Benjamin Franklin, the USA was not so promising as China or even South America before the end of Napoleonic wars. Gruber studied with Boskovic's Viennese collaborators and helped to glorify the Franklin's fame all over Europe. Jurij Vega and other Gruber's students discussed Franklin's electricity ideas. Gruber also studied Humboldt's American measurements. Humboldt described in detail the connections between electricity and magnetism without mentioning Gruber's work, but he eventually criticized Gruber's measurements of *fata morgana* above Cerknica Lake (1793),[80] because Gruber didn't precise the volume, height, or site of his *fata morgana*.

Gruber devoted a lot of attention to the USA Jesuits and helped Carroll to rebuild the USA Jesuit hierarchy with the Jesuits' Schools. On April 25, 1803, the former USA Jesuits wrote to the first USA Bishop Carroll from the Counties Charles and St. Mary's about Papal approval of Gruber's Jesuits. They knew that Gruber is rebuilding the Jesuit Society worldwide and they wished to join him.[81] On May 25, 1803 Carroll[82] and the Bishop Charles Neale († April 1823) of Baltimore told Gruber that 13 former Maryland Jesuits asked to join Gruber's Society. They were descendants of 5 Jesuits who entered Maryland with their leader Father Andrew White in 1634. They were prepared for Papal suppression in 1773 when 21 Jesuits of Maryland and nearby lands joined their former Jesuit property into a trust while they awaited the renewal of the Society.[83]

[82] John Carroll (* January 8, 1735 Upper Marlboro in Maryland; SJ September 7, 1753 Watten; † December 3, 1815 Baltimore).

[83] Kuzniewski, 1992, 57.

The New World followed the modern capitalistic views of property while the goods of the helpless European Jesuits mostly passed to the local governments.

Gruber received Carroll's letters dated on March 10, 1803 and May 25, 1803 in the USA, together with a shorter one dated on September 21, 1803. He warmly accepted Carroll's suggestions and on March 12, 1804[84] answered that he will send his Jesuits from Russia and even from England to help the USA Jesuits.[85] Gruber certainly had enough men among the English Jesuits, but his Russian Jesuits did not know the English language well enough. In Baltimore Carroll used Gruber's authority to appoint Robert Molyneux as the superior of the USA Jesuits on June 10, 1805.[86] For his negotiations with Molyneux in his letters dated on May 9/10, 1805, Carrol cited Gruber's authority as we could read in Gruber's handwritten copy preserved in Georgetown Archive.[87] Between June and October 1805 the new superior Molyneux renewed the oaths of the USA Jesuits, but Carroll did not rejoin them. In 1813 there were just 50 Jesuits in the USA,[88] but in the mid-20th century a quarter of all Jesuits lived in USA,[89] in 1965 as much as 8393, and in 2000 only 3635.[90] The USA Jesuits had great influence on American history of science overestimated opinion about the congeniality of Kircher and other Jesuit scientists. New York Jesuit schools founded in 1684 and 1808 worked just for few weeks, but others in Fordham, Saint Louis, or Georgetown were much more successful.

The English laws prohibited studies in the Jesuit or other Catholic schools in 1581 and 1603;[91] St. Omers was established to train Catholics and Jesuits who were brave enough to enter England illegally. There are no straightforward data about the philosophy or mathematics curriculum in 17th Century Belgium Jesuit Colleges, but they probably followed the Mathematician Clavius' Roman reforms,[92] and did not permit the use and possession of the new fashion watches among students, although they were pretty inexpensive.[93] In Gruber's time the English ceased the persecution of the Jesuits. Thomas Weld gave to the Jesuits a nice castle Stonyhurst in Lancashire. Gruber negotiated with the elderly Father William Strickland[94] to appoint Marmaduke Stone as the provincial of England with all Scottish and Irish missions included on March 1, 1803. The English Jesuits joined the Gruber's Society on May 22, 1803.[95] On August 19, 1803 Gruber described to Stone the influences of the former novitiates in the English Jesuit Province. The Novitiate in Watten, 5 miles from St. Omers,[96] worked until 1762, and the other novitiate in Ghent worked until 1773. John Carroll entered the Watten Novitiate on September 8, 1753 after he finished his studies of humanistic in St. Omers. His leader in the novitiate was Henry Corbie (Clorby, * April 14, 1700 Sussex; SJ September 7, 1722 Watten; † June 14, 1765 Ghent) who later became the provincial of England.[97] With historic examples Gruber put forward the great importance of the feast performed on the opening of the novitiate for 14 novices in Hodder Place near Stonyhurst on September 26, 1803. The preacher with 11 scholastics headed the introductory section, and the leader of the novitiate became the Father Charles Plowden (Simons, Simeon, * May 1, 1743; SJ September 7, 1759 Watten; † June 13, 1821 Jougne in France), later rector of Stonyhurst (1817-1819) and provincial between the years 1817-1821. Gruber highly praised Stone's work for the spiritual growth of the English novices on February 21, 1804 and on April 21, 1804,[98] because he expected much from his English brothers Jesuits. The Stonyhurst lecturer of physics and Natural Philosophy was Walter Clifford (* March 13, 1773; SJ November 2, 1803 Stonyhurst; † July 23, 1806 Palermo) who wrote his lectures on July 1, 1822.[99]

The Georgetown College was founded in 1789 as the first educational establishment in the District of Columbia, before the formation of the federal district and the birth of the City of Washington. The first Carroll's proposals of 1788

mentioned the lecturing on »*Arithmetic's, the Branches of Mathematics*«, but not explicitly physics.[100] The friend of 3rd Georgetown College president William DuBourg, Lady Joustine Douat, gave 15 shillings for the Georgetown College visiting young students on May 11, 1798.[101] The Old North Building was erected between 1791 and 1808 and served until 1905. The Observatory was erected in 1843.[102] Curley taught in the Washington Seminary, the future Gonzaga College, before he joined the Jesuits in 1826. He became professor in Georgetown in 1831 and in 1834 began to teach natural philosophy and chemistry. After the observatory was built in 1843 he determined the true meridian of Washington City there and published about the *Electric Rheometry* with the Smithsonian Institute.[103] Between the times of Franklin and Joseph Henry during the first century of USA, the Americans did not produce first rate scientists.[104]

Gruber's student Dzierożynski[105] was the most successful among the Americans. He began as the professor of mathematics, physics, philosophy,[106] and (dogmatic) theology in Polock Academy. Between the years 1794-1809 he was Gruber's student in Polock. After finishing his philosophical studies he lectured on French language, physics, music, and grammar in Gruber's *Collegium Nobilium* in Petersburg,[107] and after finishing theological studies Dzierożynski lectured on Natural History, Geology, and Mathematics in Mogilev. According to de Maistre's suggestions the Tsar Alexander made Polock Academy the chief Jesuit school in Russia on January 12, 1812. In 1819/20 the Polock Jesuits lectured on the mathematical solving of chemical problems and the trigonometric problems in physics,[108] just before the Tsar exiled Russian Jesuits.

Conclusion

Slovenia is hundreds times smaller compared to USA, Russia, or China. Nevertheless, with Hallerstein and Gruber, Slovenians made their way into Chinese and Russian history. They even wrote some of the most important pages of it because Beijing astronomer Hallerstein published the greatest number of scientific works in Europe. Gruber enabled the continuous development of Jesuit Order in Russia, and eventually tried to reestablish the Chinese and USA Jesuit organization.

The Baron Hallerstein belonged to the nobility on his father side and to the new Barons on his mother's Erbergs side. Gruber was armory's son and therefore a member of the 3rd class. Those differences in origin anticipated their different orientation towards technology&science although as the Jesuit priests they belonged to the same 2nd class. Their achievements are comparable, even if Gruber was an engineer and diplomat, while Hallerstein was astronomic observer and scientist. In his primary scientific orientation Hallerstein was experimentalist, while Gruber mostly relied on technology and inventions. Their birth dates are nearly forty years apart. Hallerstein never met Gruber because he left Europe before Gruber's birth and never returned. As a priest Hallerstein would welcome Gruber's Russian political opportunities, but as a scientist he certainly preferred his privileged position on the top of Beijing Mathematical Bureau. On the other hand, the young Gruber would welcome more influential position in Ljubljana to support his planned building of the Argonaut connection between the Adriatic Sea and Sava River during the early regime of the Emperor Josef the 2nd.

Comparative studies are rare in the history of science especially in our way of parallel research of two different personalities working in different metropolis on non-similar research topics. The only things Hallerstein and Gruber had in common were their mutual Slovene nationality, Jesuit priesthood, 18th century, and success in the East. They eventually had pretty comparable starting positions with similar linguistic-mathematical talents, but varied circumstances decided their different fates and destinies. Gruber wanted to work in China without ever winning a chance to do so, but we could imagine him in Hallerstein's Mathematical Bureau if Jesuit Order would not get suppressed in 1773. Just before the suppression, Gruber accomplished his final wows for the Jesuit order which was just about to collapse. He was predestined to carry the torch of science&technology to the East during the worst times his order ever had. Science&technology for *the greater glory of the Lord* was the motto of Hallerstein and Gruber, and both got their personal glory out of it as the best Mid-European literati ever working in the East.

AN EPISTOLARY LAB: THE CASE OF PARHELIA AND HALOS IN DESCARTES' CORRESPONDENCE (1629-1630)[1]

Delphine BELLIS
Universiteit Utrecht, THE NETHERLANDS
delphine_bellis@hotmail.com

Abstract

The aim of this paper is to provide insight on Descartes' experimental philosophy as it is recorded in his correspondence. Because Descartes articulates very precisely experience with theory, he excludes any random collection of experimental data if they cannot be inserted into a theoretical framework. From the record of the apparition of parhelia in 1629 in Rome, the epistolary communication between Mersenne, Descartes and Gassendi presents us three different attitudes toward observation, its interpretation and the possibility to relate it to other phenomena.

Descartes' physics has often been seen as a mere theoretical work or, even worse, as an imaginary production, far from being in touch with experimental reality.[2] Nevertheless, if we pay more attention to Descartes' own words on the topic, we may draw quite a different picture of his natural philosophy. In several of his works, experience is theorized as a way to choose between several competing explanations of physical phenomena, all being coherent with physical principles and equally possible from a theoretical point of view. But, useful as they might be to understand the role experience can play from a theoretical point of view in Descartes' physics, these texts do not always make fully explicit what precise role experience plays in the concrete making of Cartesian natural philosophy, nor what Descartes considers to be a valid experiment. To have a more accurate view on this, we must turn to Descartes' correspondence. There we discover him commenting on phenomena, discussing of several experimental devices or fully realized experiments, some of them being notably performed by others. This considerably challenges the picture Descartes built of himself as an independent thinker[3] who would have isolated himself from the world to think with his own intellectual means.

[1] Research for this paper was made possible by NWO, the Dutch Organisation for Scientific Research. I would like to thank Mihnea Dobre and Tammy Nyden for their useful suggestions on an earlier draft of this paper.

[3] Peter Dear depicts Descartes as "the apostle of the individual knower" (*Discipline and Experience. The Mathematical Way in the Scientific Revolution*, Chicago and London, The University of Chicago Press, 1995, p. 94).

The collection of experimental data in relation to Descartes' epistemology

It is difficult to establish a clear demarcation between experiment and passive observation in Descartes' texts.[4] From a linguistic point of view, Descartes establishes no difference between "experience" and "experiment". Whereas he could have used, at the time, the French word "experiment",[5] he does not so. "Expérience" therefore refers, for him, to simple observations as well as to contrived experiments. This can be accounted for, as we are going to see, by Descartes' double appeal to experience.

Indeed, experience and experiments play a central role, in Descartes' natural philosophy, because an *a priori* natural philosophy cannot be deductively established in all its details and because, as a consequence, Descartes has to rely on a methodical dialectics of effects and causes. From the general principles of matter and motion established by metaphysics, it is possible to elaborate several possible explanations which account for the phenomena. But to decide what explanation is the one really working in nature, one has to appeal to experience.[6]

In a letter to Morin, Descartes indicates: "I should add also that there is nothing circular in proving a cause by several effects which are independently known, and then proving certain *other* effects from this cause."[7] Experience plays then a role at two levels: first to collect facts produced in nature to go from them to the explanatory structure of bodies, and second to conceive other effects which can be produced by such a set of mechanical properties. The mechanical structure which has gained plausibility from its compatibility with the phenomena from which it was designed, will gain further confirmation in its capacity to agree with other phenomena which are different from the first ones.

As a consequence, experience has no value independent of the possibility that it be linked to all the phenomenal aspects of the world through a kind of demonstration or series of demonstrations.[8] Descartes defends a holistic account of natural philosophy in which experience serves to complete the whole of natural philosophy. In the Lettre-préface to the *Principles of Philosophy*, he writes:

> "I am also very well aware that many centuries may pass before all the truths that can be deduced from these principles are actually so deduced. For the majority of truths remaining to be discovered depend on various particular observations *which we never happen on by chance* but which must be sought out with care and expense by very intelligent people."[9]

In that case (which corresponds to the second level of experience), Descartes does not consider experiments as what one can find by chance when "looking around" but experiments are supposed to answer specific purposes in the search for truth in natural philosophy. They must therefore be designed according to theories and hypotheses already conceived.

The corollary of this valorisation of experience depending on theoretical prerequisites is the critics of random experiences. It is not legitimate, for Descartes, to rely on approximate experimental results to invalidate a law. This is for example the case with the law of refraction: in 1639, he criticizes, in a letter to Mersenne, an opponent for trying to refute his law through experimental measurements of refraction by saying that this endeavour is not better than "to show, with a poorly-constructed set-square, that the three angles of a triangle are not equal to two right angles."[10] Demonstrations in optics are comparable to those in mathematics and, for this reason, are not liable to mere empirical refutation. But, on the reverse, it is not absolutely pointless to get experimental confirmation of the law of refraction, once it has been theoretically demonstrated. This is the reason why Descartes thanks Debeaune for his exact measures of refraction.[11] In this case, the results confirming Descartes' law of refraction are a proof that the experiment was correctly conducted. On the other hand, in 1632,[12] Descartes himself devises, for Golius, such an experiment to verify his sine law. He details to his correspondent an experiment to measure refractions from air into water. Note that this is not an experiment he seems to have performed himself. But Descartes imagines a specified use for this device, in agreement with his own law of refraction. The procedure does not

consist in listing in tables some measurements obtained directly with the instrument through an inductive process,[13] but to anticipate by a geometrical construction what is to be seen on a ruler immersed in water. He advises Golius to draw first on a ruler the marks according to which refraction is supposed to happen according to a geometrical construction elaborated from Descartes' law of refraction. Then the ruler is immersed into water so that the experimenter can observe the coincidence between the geometrical construction and the physical phenomenon. The experimental device is therefore only meant to read into experience what has already been deduced and drawn by optical theory and geometry.

Descartes in his experimental network

As we can see with the examples of Debeaune and Golius, Descartes is also interested in experiences he does not perform himself. Among the experiences discussed in Descartes' correspondence, one finds comments on experimental records as much as on experiments really performed by Descartes himself. This is made possible mainly through Mersenne's large epistolary network which allows Descartes to get more experimental data than the experiences he can perform by himself could provide him with.

Apart from the well-known role Mersenne played in scientific communication across Europe and from his support to experimental philosophy, Descartes' correspondence can give us an accurate insight on what the philosopher considers to be important in experience by comparison with what other experimenters do and with what they find relevant for natural philosophy. In these epistolary exchanges, this is not only the way scholars communicate on experimental results which is to be seen, but also several divergent aspects of the status of experience in natural philosophy in the first half of the seventeenth century.

For Descartes, as we have seen, only experiences that could be integrated into a coherent study of nature relying on theoretical assumptions could be relevant, regardless of any attraction for curiosities. Therefore, the stake was to integrate discrete events into a more general "system of the world,"[14] so as to access a universal knowledge of nature. Particular phenomena are the occasion for natural philosophers to enrich their general framework and to apply it to specific aspects of nature. But from a traditional, that is to say Aristotelian, point of view, experience was related to the way things happen in nature in general and not to the way a particular event had occurred. This conception of experience changes during the 17th century, but most of the time we can find a mix of these two conceptions of experience, even often in the same author's writings. When they are not part of an every-day experience which can be easily recognized by everyone, experiments are not evident data which, by themselves, can confirm general theories on nature. Observations are not always unproblematic, even if they do not imply any specific technical apparatus or any determinate experimental procedure. This is eminently the case when observations are actually *reports* of observations. Reports always mean a selection of what is considered to be the set of appropriate data by opposition with superfluous or contingent or inessential data. In that case, the natural philosopher has to distinguish between important elements and irrelevant details which do not allow elaborating a scientific explanation.

Moreover, the reported observations first have to be established as facts, that is to say as serious pretenders to integrate the realm of experience, before they can be dealt with in a scientific manner. Correspondence is particularly suited to record and report discrete events, detailing their appearances and the circumstances under which they occur. But, at the same time, a letter is only a substitute for a direct contact with the experience in question. Therefore, what is at stake is to pick out what the correspondents consider to be the appropriate elements to be communicated about an experience. To give more plausibility to observations, reports of experience could also be constructed as narrative, and not as mere description of facts.[15]

From this point of view, the phenomenon of parhelia which we will examine more in detail is very revealing, because it was reported as a spectacular and rare event, nearly an historical one (the title of Gassendi's explanation published in Amsterdam indicated for example on what date it occurred).[16] But, on the other hand, it was integrated into a general explanation relying on optical theories, on matter theories and these approaches were tentatively extended to other so-claimed related phenomena (like halos, rainbows and candles).

[13] I do not intend to claim that Witelo or Alhazen followed such an inductive procedure themselves. On optical tables which were not the resultant of raw observation, but more often of a logarithmic formula, cf. Dear, *Discipline and Experience*, *op. cit*., p. 81.

[14] Descartes to Mersenne, 12 September 1638, AT II, p. 355.

[15] Cf. Peter Dear, *Discipline and Experience, op. cit*., p. 75.

[16] *Phaenomenon rarum et illustre Romae observatum 20 Martij Anno 1629*, etc., Amsterdam, Gerard, 1629.

The example of halos and parhelia: from the apparition in Rome in 1629 to the *Météores*

I would like now to turn to a case study at the crossroads of optics and meteorology in Descartes' correspondence: the explanation of the parhelia of 1629. Whereas optics was considered by scholastic philosophy as mixed mathematics (a branch of geometry), meteorology belonged to a more physical and uncertain realm. The conjunction of both domains in the study of this phenomenon testifies to the change occurring in scientific boundaries at the time. Noteworthy is then the way experience is articulated with theoretical analysis in the explanation of such a phenomenon. One also has to underline that optics itself is then evolving from the domain of geometry to one of a mix between mathematics and natural philosophy.[17] And Descartes himself presents his *Dioptrique* as a mix of mathematics and (natural) philosophy.[18]

What is most striking is that the 1629 parhelia are studied by numerous scholars throughout Europe, whereas most of them did not see the phenomenon. All the explanations therefore develop from reports of observation, exchanges of letters, and reconstructions based on comparisons with other observations actually performed.

On March, 20th, 1629, five suns shone in Rome. Cardinal Barberini sent a drawing and description of the display to Peiresc[19] who in turn sent some copies to the brothers Dupuy[20] and Gassendi.[21] On 14 July 1629 Gassendi had given an explanation and description of the phenomenon of the parhelia to Reneri, one of Descartes' friends. This letter was published first by Reneri,[22] and then by Gassendi himself.[23] The description of the phenomenon might be based on the observation made by the Jesuit Christoph Scheiner.[24] Descartes was intrigued by the phenomenon and decided to give his own explanation. Perceiving a similarity between the appearance of the parhelia and that of a rainbow, he was then led to study all sublunar phenomena.[25] His explanation of parhelia will later be published in the *Météores*.[26]

Let us now turn to the subsequent epistolary exchanges it gave rise to between Descartes and Mersenne. On 18 December 1629 and in January 1630, Descartes answers to letters from Mersenne in which the Minim reports the observation of coloured circles around a candle.[27] At first, Descartes seems sceptical about those observations. Mersenne had apparently tried to connect this phenomenon to the luminous circles appearing around the sun, like in the case of halos appearing together with parhelia. But Descartes rejects this analogy on the ground that the order of the colours is different in the two cases.

The rejection of Mersenne's analogy seems nevertheless to conflict with Descartes' later claim in a letter to Morin: "I maintain, therefore, that analogies of this sort are the most appropriate means available to the human mind for laying bare the truth in problems of physics."[28] Descartes requires that any explanation in physics be based on one analogy. But this methodological requirement is rooted in his metaphysical conception of matter as being one and the same everywhere and at every scale. What is therefore at stake is to find the right analogy. This shows that, for Descartes, one should not make a too widespread and thoughtless use of analogy when comparing our visual data, but a moderate and reasoned one. This reasoned use of our senses to collect data gives rise to a certain attitude of the natural philosopher. He is the one who has learnt to see, as is manifest from what Descartes declares in the *Sixth Replies*:

> "[W]hen we say 'The reliability of the intellect is much greater than that of the senses', this means merely that when we are grown up the judgements which we make as a result of various new observations are more reliable than those which we formed without any reflection in our early childhood [...]."[29]

[17] This is also true among Aristotelian philosophers: cf. Aguilonus, *Opticorum libri sex*, Antwerp, Plantin, 1613, preface, s.p.

[18] Descartes to unknown, [27 April 1637?], AT I, 370.

[19] Cf. Peiresc to Dupuy, 16 April 1629, in *Lettres de Peiresc publiées par Philippe Tamizey de Laroque*, Paris, Imprimerie Nationale, 1888-1898, II, pp. 72-73.

[20] Cf. Peiresc to Dupuy, 20 April 1629, in *ibid.*, II, p. 76.

[21] Cf. Gassendi to Peiresc, 21 July 1629, in *ibid.*, IV, p. 201.

[22] Letter of [14] July 1629, published as *Phaenomenon rarum et illustre Romae observatum 20 Martij Anno 1629*, etc., *op. cit.*

[23] *Parhelia, sive soles quatuor qui circa verum apparuerunt Romae die XX mensis martis, anno 1629, et de eisdem Petri Gassendi ad Henricum Renerium epistola*, Paris, Vitray, 1630.

[24] But there is no definite textual evidence about Scheiner as being the source of the observation: cf. Walter Tape, Eva Seidenfaden, Gunther P. Können, "The Legendary Rome Halo Displays", *Applied Optics*, Vol. 47, No. 34, 2008, H72-84.

[25] Descartes to Mersenne, 8 October 1629, AT I, 23; Descartes to Mersenne, 13 November 1629, AT I, p. 70.

[26] AT VI, p. 355.

[27] AT I, pp. 83-84, 97-99, 106.

[28] Descartes to Morin, 12 September 1638, CSMK, p. 122.

[29] CSM II, p. 295.

From this point of view, so-far unseen observations play a privileged role in the constitution of a natural philosophy, since they are not liable to the same precipitation of judgement, because of their lack of familiarity to the observer. On the contrary, the false evidence of an experience which has not enough been analyzed by reason is a dangerous trap.[30]

So why is Descartes sceptical about Mersenne's observation in that case? Mersenne apparently tried to sustain his claim by referring to the testimony of an observation made by Gassendi, which indicates that the Minim appeals to a consensual and collaborative conception of experience. Mersenne apparently also tried to insist on Gassendi's talents as an observer who claims to have observed several times that, in the case of parhelia, the apparent diameter of the corona is of 45°. That is indeed what Gassendi had conjectured in his *Phaenomenon rarum*[31] and Descartes himself is ready to agree with that specific value, without excluding others. Kepler had already noticed that the diameter of the coronas appearing around the sun was of 45°.[32] That Descartes and Gassendi take up this value is certainly due to their reading of Kepler as much as to real observations. While rejecting as impossible Mersenne's observation of the colours around a candle, Descartes manages to account for Gassendi's by assuming that he took for one two coronas which were partly confused.

As I noted, Mersenne must have alluded to an experience attributed to Gassendi to sustain his analogy between the corona around a candle and solar halos. This "experience" can indeed be related to Gassendi's description of coronas around the sun associated to the phenomenon of parhelia. In his letter to Reneri,[33] Gassendi reports that the sun was circled by two incomplete rainbows of diverse colours. Descartes, to whom this text was transmitted by Reneri, here claims that, in agreement, as it seems, with Gassendi's experience, every corona or iris displays more or less the colours of the rainbow, and not the colours Mersenne claims to have seen around the candle.[34] The colours listed by Descartes in his letter to Mersenne are indeed close to the ones Gassendi identifies in a solar halo observed in 1623: red in the inner part, then yellow, and green in the outer part.[35] This observation is certainly the basis for Gassendi's conjecture on the types and order of colours of the coronas observed together with parhelia in his explanation of a phenomenon he has not himself directly observed.[36] Mersenne seems to have had access to some of these so far unpublished reports of observations made by Gassendi[37] and in May 1630 he will send Gassendi's description of a corona to Descartes.[38] The information that was available to Gassendi lacks precision as to the diameters and thickness of halos, the distance between the suns and their size, as Gassendi himself recognizes.[39] One therefore understands that he relied on his collection of former, related observations to enrich the description of the 1629 parhelia. Gassendi thus appealed to analogy between real and reported observations to build his explanation, whereas Descartes argues from a more theoretical basis, postulating a homogeneity between determinate optical phenomena —this postulated link being the source of *Les Météores*— and *afterwards* using Gassendi's supposed observations to reinforce his position.

Descartes eventually accounts for coronas around a candle by a partial dispersion of light inside the eye (what he calls *lumen secundarium*).[40] The source of the parallel Descartes draws between his conception of secondary light rays inside the eye and the light dispersed around the main ray when entering a dark room through a small hole certainly is Witelo's definition of secondary light in his *Perspectiva*.[41] But here Descartes modifies the meaning of the term to apply it to light rays inside the eye. Deviating from the straight line along which the main light ray is refracted in the crystalline, some secondary light rays coming from the same source can be spread and impressed on the retina around the image-point created by the main light ray, giving rise to the optical illusion of coronas around the candle.[42] According to Descartes, this phenomenon is only due to a specific modification of some internal parts of the eye (provoked for example by a pressure exerted on it which could modify the crystalline's configuration).[43] Descartes appears close to Galileo who also relies on the eye's configuration and on the refraction of light rays inside the eye to account for coronas seen around candles.[44]

Descartes' correspondence thus appears as a laboratory where he does not only elaborate his concepts and theories, but also where he "experiments" with his correspondents on matters of natural philosophy through the analysis of observations. But several figures of the observer appear throughout that correspondence. Mersenne, the eclectic incautious observer, reports as much as he can what he has seen, without being really able to analyze his observations. Gassendi is a systematic collector of singular observations, but he is also able to compare them to elaborate explanations. Descartes is the most theoretical experimental philosopher of the group: he needs to gather experimental data (which corresponds to the first level in his methodology) but accepts observations when they are at least coherent with some theoretical positions (his own as well as others' like Witelo and Galileo).

THE EMPIRICAL ELEMENT IN DESCARTES' PHYSICS AND ITS RECEPTION BY SPINOZA

Epaminondas VAMPOULIS
Department of Philosophy, University of Patras, GREECE
vampouli@upatras.gr

Abstract

Cartesian physics adopts an epistemologically realistic worldview based on the doctrine of the truthfulness of clear and distinct ideas. But the application of this doctrine on physics is closely related to the demonstration of the existence of material objects and thus implies an allusion to experience. Thus, Descartes' theory concerning the principle of material objects, although claiming to be a mathematical theory, seems to allow experience to play a crucial role. In his first published book, Spinoza gives a "more geometrical" transcription of Descartes' metaphysics and physics. Spinoza follows a rigid deductive method leading in a deterministic way from the first principle to their consequences and his exposition of Cartesian physics relies strongly on a purely intellectual grasp of the nature of corporeal substance that our senses cannot reveal. But things become more complicated once we realize that Spinoza's text contains some elements that are not of a purely rational origin.

Introduction

One of the main features of the Cartesian natural philosophy is reputed to be the absence of a rigorous experimental methodology and of facts originating from experience. There are, of course, several points in Descartes' work that contradict such a generalization. I think that the role of experience has indeed often been underestimated in the secondary Cartesian literature, as the image usually found in this literature is the grotesque image of Descartes constructing his physical science with nothing more than elements of a purely rational origin. I do not intend to reproduce this conception of Cartesian science, and anyway my paper will not focus on the general features of Cartesian science. My aim is a much more limited one, as I intend to examine the impact of some aspects of Cartesian science on the work of Spinoza and to show that at least in some cases the absence of the empirical element in Cartesian science has led Spinoza to results that can be taken to be the ultimate consequences of the absence of an elaborated experimental attitude.

General remarks

It is a well-known fact that Descartes is the philosopher who proposed and organized in a rigorous manner the mechanical worldview. He is the philosopher who deliberately worked on a theory providing the metaphysical basis for the conception of matter as pure geometrical extension. For Descartes matter is identified with an extension that does not possess any qualitative differentiations. Such a reduction of matter to geometrical extension and of all the qualities of the former to properties geometrically defined is attained at the cost of a strict dualist distinction between body and mind.

The material world, thus, consists according to the Cartesian mechanical worldview in nothing more and nothing less than geometrically conceived extension. Descartes cleanses matter of any property that cannot be translated into the vocabulary of geometry. In other words, bodies do not have the substantial forms that according to medieval scholastic philosophy constitute the element of individualization. Also, bodies do not possess any internal tendency to accomplish a task, a goal. Cartesian physical philosophy excludes any kind of teleological explanation since bodies obey only mechanical necessity, the necessity of extension, motion, and figure. Motion and rest thus become, ontologically speaking, mere modes of a substance, that is states of bodies moving in a homogeneous Euclidean space. But such a conception leads inevitably to the problem of the cause of motion as long as geometrical entities do not possess an internal principle or a tendency which puts them in motion. Given this, it can be inferred that matter is by its nature in rest and must be put in motion by an external cause[1].

The cause that sets matter in motion according to Cartesian theory is of a transcendent nature. It is God who bestows motion to matter, and He does it as He recreates at every instant all that there is in the world. As Descartes says in his work *The Principles of Philosophy*, "from the fact that we now exist, it does not follow that we shall also exist a moment from now, unless some cause (that is, the same one as that which first produced us) continually produces us, as it were, anew; that is, conserves us."[2]. What is at stake here is Descartes' theory of continuous creation, a theory playing a significant role in his physics[3]. Because God does not only recreate at every instant all that exists but also "in now maintaining the world by the same action and with the same laws with which He created it, He conserves motion"[4]. Such a statement proceeding from Descartes' pen has multiple effects on his conception of motion, but it will be enough to note here that for the Cartesian physical philosophy the action through which God maintains the world is at the origin of the laws that govern the distribution of motion and rest between bodies.

The whole structure of Descartes' natural philosophy finds its basis in a metaphysical theory. This theory sets the traditional problems of the theory of knowledge on new ground. Descartes' theory of knowledge consists above all of a new way of defining the thinking substance and man's ability to grasp certain knowledge. The completion of the enterprise is described in a text emblematic for seventeenth century metaphysics, the *Meditations on first philosophy*. This text, divided into six meditations that each mark a step towards the conception of indubitable knowledge, has as its starting point a systematic and well-organized leap into total uncertainty. This leap is based on some arguments that in Descartes' philosophy are supposed to show that we cannot be sure even of the truth of simple mathematical propositions such as the sum of two and three.

By contrast with what takes place during the first meditation of the *Meditations on first philosophy*, the second meditation introduces a new issue. Descartes, or the unidentified narrator in Descartes' text, starts to ask himself if the universal doubt leads to some kind of knowledge, if he knows anything at all. This questioning will lead him to the famous "*ego sum, ego existo*".

In such a metaphysical theory that establishes the mind's ability to grasp clear and distinct ideas without any reference to the outside world there is no place for experience, or, if there is, this place is well determined. Thus, in the *Principles of Philosophy*, experience is given a significant role in the first section of the second part of the book. In this section Descartes refers to experience in order to prove that "we know with certainty that material objects exist."[5] The existence of bodies is thus closely related to what we learn through our senses. According to Descartes' demonstration, the existence of material substance is obvious as long as bodies in motion provoke in us multiple sensations. Against this assertion an objection can easily be raised: are we sure that bodies and their motion is what causes our sensations? Because one might argue that God produces in our minds the idea of the material substance without even having to create this substance. But, as Descartes replies to his potential objector, God is not a deceiver but a guarantor of the truthfulness of what we clearly and distinctly perceive.

---

[1] This is exactly what Descartes has to admit in a letter (August 1649) to More: "I agree that 'if matter is left to itself and receives no impulse from anywhere' it will remain entirely still." (Descartes, 1991a, 381).

Spinoza and the problem of the existence of matter

The importance of the problem of matter's existence is emphasized in the first published work of Spinoza, a presentation of Descartes' metaphysics and physics according to the geometrical method, published under the title *Principles of Descartes' Philosophy*. We should not forget that Spinoza's philosophy occupies a central position in the movement of early modern philosophy which deals with the foundations and the ultimate consequences of the mathematical conception of nature. Besides, it is a well-known fact that Spinoza was in contact with some eminent scientists of his time like Oldenburg and Boyle, and closely followed the achievements of contemporary science.[6] His correspondence also manifests his interest in physical problems. Of course, there is no evidence that Spinoza read any of Galileo's texts, or at least no evidence drawn directly from the extant sources of Spinoza's life and work.[7] The lack of any reference to Galilean physics in Spinoza's writings cannot, however, negate the assumption that he was well aware of its fundamental concepts.

In order to return to the problem of the role of experience in Spinoza's first published work, let us examine the relation between physics and metaphysics as presented in the *Principles of Descartes' Philosophy*. The problem we are facing is one found between the first and the second part of this work. It is a problem concerning the association of the demonstration of the material substance's existence to the knowledge of matter's essence. Is there any place in this passage for experience? And if there is, as Descartes has already tried to show, how does Spinoza treat experience?

In Spinoza's presentation of the Cartesian theory, it is clear that what pertains to the problem of God's veracity and what is part of a rational physical theory belong to two totally different levels. Thus, Spinoza separates what is intrinsically woven together in Descartes' philosophy. In his work the demonstration of the existence of bodies is presented at the end of the first part of his book, in the part dedicated to metaphysics. Despite the fact that according to Descartes a rational physics must find its object only by means of a metaphysical demonstration, Spinoza does not accept as a part of a rational physics what is of a metaphysical origin and what necessitates a reference to our experience. Physics is for Spinoza the rational study of the properties of material substance.

Evidently, such an approach transforms Cartesian physics into a theory defined in purely geometrical terms and ordered according to the rules of deductive structure. This is exactly the goal that Spinoza tries to achieve in his *Principles of Descartes' Philosophy.* It is true, of course, that as long as Spinoza follows the Cartesian doctrine, he has to give to experience a role in the demonstration of the existence of bodies. But this role is not one that can find a place in the context of a rational physics. Spinoza reserves the second part of his work for a physical theory of a geometrical origin and does not want to combine an element not rigorously deductive with his systematic presentation of a theory identifying matter with geometrical extension.

Spinoza's presentation opens with a set of definitions and axioms. In this set, there is no mention of elements of an empirical origin, with only one significant exception in the twelfth axiom. This axiom will later be used by Spinoza in the demonstration of a proposition treating the motion of bodies submerged in a fluid. Even if this theory is basically of an auxiliary character, we must confess that the theory of motion in a fluid is the part of Descartes' physics which tries to reconcile the predicted results of collisions between bodies with the empirical lessons on that matter.

The problem of inertial motion

If we wish to examine in a more subtle way the use of experience in Spinoza's early work, we shall have to search for those propositions which, although drawn from Descartes' text, have in Spinoza's work demonstrations that differ from the ones given by the French philosopher. These demonstrations are usually proposed by Spinoza in an attempt to render the physical theory he is exposing more rigorous from a geometrical point of view. Such is the case, for example, of the two demonstrations he gives when presenting a crucial proposition for Cartesian physics, a proposition which forms a part of Descartes' second law of nature. Spinoza writes: "Every body which moves in a circle, as for example, a stone in a sling, is continuously determined to go on moving along a tangent."[8]

In Spinoza's formulation of this proposition a couple of points merit our attention. First of all, we have to notice that this theorem is followed by two demonstrations, each of them containing an allusion to a different geometrical theory. The first one refers the reader to two propositions of the third Book of Euclid's *Elements*, while the second one proceeds in a way supposedly borrowed from Archimedean geometry. Secondly, we must underline the fact that these two demonstrations do not have any equivalent in Descartes' text. Descartes simply takes for granted the fact that a stone rotated in a sling and describing a circular path, is in fact inclined to move along the tangent of the circle. So, given that Descartes never really

---

[7] S. Nadler (1999, 111) conjectures that Spinoza had lessons in the new science and Galileo's physics in Van den Enden's school.

[8] *Principles of Descartes' Philosophy*, II, proposition 16 (Spinoza, 1988, 278).

tries to demonstrate this proposition, these demonstrations can be seen as Spinoza's contribution to the theory of inertial motion.

Spinoza's first demonstration of the theorem is of a special interest for the scope of our study. It is based on an analysis of the example of a stone rotating in a sling, an example taken from a section of the second part of Descartes' book where the French philosopher writes: "when the stone A is rotated in the sling EA and describes the circle ABF, at the instant at which it is at point A, it is inclined to move along the tangent of the circle toward C. We cannot conceive that it is inclined to any circular movement: for although it will have previously come from L to A along a curved line, none of this circular movement can be understood to remain in it when it is at point A. Moreover, this is confirmed by experience, because if the stone then leaves the sling, it will continue to move, not toward B, but toward C. From this it follows that any body which is moving in a circle constantly tends to move away from the center of the circle which it is describing."[9]

Spinoza in his demonstration witnesses his knowledge of the geometrical method. According to this method every proposition must be demonstrated, unless it constitutes an axiom. So, Spinoza decides to demonstrate the proposition left by Descartes without demonstration. Spinoza wants to show that the path followed by the stone is well determined and that the tangent is the only path compatible with the geometrical principles of a rational physical theory.

Spinoza's demonstration is composed of two steps. In the first one, he makes it clear that any given moving object continues to move in a straight line and if it does not, it "is continuously prevented by an external force from continuing to move in a straight line. If this force ceases, the body of itself will continue to move in a straight line"[10].

After these general remarks, Spinoza passes to the study of the specific case of a body moving in a circle: a body rotating in a sling "is determined by an external cause to continue to move along a tangent."[11] But Spinoza has told us a few lines earlier that it is an external force which *prevents* the mobile from moving in a straight line. How can we explain the fact that Spinoza attributes to an external cause the two different and even opposed tasks just described? On the one hand, he holds that it is by an external cause that a body is prevented "from continuing to move in a straight line", and then he contradicts himself when he argues that an external cause is what determines a stone in a sling to continue to move along a tangent.

Let us reiterate the basic components of our problem. The stone does not continue its motion in a straight line because of a force other than the force of its own movement, this is clear for Spinoza who states this principle unambiguously. A moving object in order to continue its motion does not require anything else because motion perseveres in its being without the need of an external force. So, the continuation of a motion in a straight line must be conceived of as nothing more than the mere fact of the conservation of a mode of the body.

It seems, though, that Spinoza misunderstands the fundamental law of inertia. The source of this misunderstanding is probably the fact that he indistinctly makes use of elements found in the demonstrations of the two parts of the Cartesian version of this law. Descartes' demonstration of the first half of the law of inertia, that is of the part that states that "when a thing is once moved, it always continues to move"[12], makes use of the principle of the conservation by God of the quantity of motion placed in matter. This sounds as if God acts as an external cause which determines matter's motion. And this is exactly the point which Spinoza transfers to the second part of the Cartesian law of inertia, when he takes the rotating stone as being determined to move on a straight line by an external cause. Spinoza holds that a rectilinear motion must depend on a cause that determines the kind of motion that will be produced.

One might conjecture here that what Spinoza means is that God, with his permanent concurrence, recreates everything at every instant and by doing so He brings about a motion that is simple, thus rectilinear. But it is easy to see that this is not the case and that Spinoza had the means to avoid any kind of confusion on this subject. It is not an external cause which determines the stone to continue to move along a tangent. Even if we accept that it is God who is the principal cause of motion, God from this point of view is not an external cause as long as He imparts to every one of the bodies in the world a certain quantity of motion. Even worse, the rest of Spinoza's demonstration shows clearly that it is not to God that Spinoza is referring when he speaks of an external cause, but to the sling. To say it more clearly, Spinoza considers the sling as a cause which determines the stone to move along a tangent.

[12] *Principles of Philosophy*, II, section 37 (Descartes, 1991b, 59).

The misuse of experience

We can now pass to the search of the cause that led Spinoza to such a remarkable misunderstanding. A lot of conjectures can be put forward, but I shall focus on one which stresses the role of experience in Spinoza's analysis. I think that it is because of a misuse of experience that Spinoza makes a mistake that normally would be obvious to any careful reader, and of course to Spinoza himself. But before taking a look at the real cause of Spinoza's mistake, we have to go back to Descartes' text. Descartes discusses the same example of the tendency to move away from the center of the circle detected in the case of a rotating stone. We can see that there is an interesting allusion to experience in the Cartesian text: "This is confirmed by experience, because if the stone then leaves the sling, it will continue to move, not toward B, but toward C."[13] Thus, it is in experience that Descartes finds a confirmation of the rectilinear trajectory that the stone will follow if there is no impediment. Leaving aside the fact that experience does not corroborate such an assumption, it is interesting to observe the way both philosophers are misled because of the fact that our sensation seems to imply that the stone rotating in a sling is at every instant determined to continue its motion on the tangent.

Both Descartes and Spinoza approach the example at hand through the lens of everyday unanalyzed experience. In the case of Descartes we are in front of textual evidence, whereas in the case of Spinoza no such evidence can be found. But Spinoza declares that the stone is determined by an external cause to continue to move along a tangent, and that this cause is the sling itself. This may plausibly be attributed to the impression that we have when we hold a sling in our hand and rotate it. We have the feeling of the sling forcing the stone to move away from the center of rotation. But this is just a false impression, because what is really happening is that the rope of the sling prevents the stone from moving upon a straight line and keeps it moving circularly.

Conclusion

It is now clear that when Spinoza is describing the sling as an external cause determining the stone to move along the tangent he is alluding to empirical evidence which is nothing more than a confused feeling. But Descartes' text which Spinoza had in his hands when he wrote his first published work, did not provide him with the indispensable skill of analyzing with a mathematical rigor what is given through experience. Spinoza's method is rigorous, of course, but it is a method of geometry, not of experimental physics.

This is why we find in Spinoza an ambivalent attitude toward experience. Obviously, he cares about what experience has to tell us, but what is lacking from his early work is an ability to translate the language of experience into geometrical terms. We have seen that he does not banish experience from the field of natural philosophy, but tries to delimitate its possible uses. One of these possible uses concerns the agreement between the previsions of a geometrical physics and the observations drawn from the real world. But when it comes to the validity of a proposition, Spinoza seems incapable of using techniques that might lead to a refined evaluation of the lessons taught by experience.

I think that one can find the same ambivalent attitude in Descartes' work. There, the empirical element is not absent, but it does not constitute a substantial part of the theory, this theory being essentially based on geometrical principles. What is more, this geometrically-based physical theory depends heavily on a theory of knowledge which is woven together with a metaphysical system rationally orientated. The whole structure of such a theory on the one hand minimizes the role of the empirical element and on the other leads to an acceptance of some elements of empirical origin without their necessary analysis.

T. NYDEN: EXPERIMENT IN CARTESIAN COURSES: THE CASE OF PROFESSOR BUCHARD DE VOLDER[1]

Tammy NYDEN
Grinnell College, USA
nyden@grinnell.edu

Abstract

In 1675, Burchard de Volder became the first university physics professor to introduce the demonstration of experiments into his lectures and to create a special university classroom, The Leiden Physics Theatre, for this specific purpose. This is surprising for two reasons: first, early pre-Newtonian experiment is commonly associated with Italy and England, and second, de Volder is committed to Cartesian philosophy, including the view that knowledge gathered through the senses is subject to doubt, while that deducted from first principles is certain. On the surface, it is curious that such a man would bring experiments to university physics. After all, in demonstrating experiments to his students, he was teaching them through their senses, not reason. However, if we consider the institutional context of de Volder's teaching, we come to see de Volder's Cartesian experimentalism as representative of a certain form of pre-Newtonian Dutch Cartesian science, as well as part of a larger tradition of teaching through observation at the University of Leiden. Considering de Volder's institutional context will help us see that de Volder's experimentalism was not in spite of his Cartesianism, but motivated by it.

This paper will describe de Volder's physics curriculum, the Theatre in which it was taught and how his work predates similar efforts in other European Universities. The second part will consider three aspects of the culture at the University of Leiden: a tradition of teaching through observation, a particular reception of Cartesianism, and an eclectic approach to the New Philosophy. The concluding portion shows how de Volder would have understood his enterprise in Cartesian terms.

De Volder's Teaching

Very few discuss de Volder today and most of those discussions are in relation to his eight-year correspondence with Leibniz. However, during his own lifetime, he was well known,[2] largely due to the form and content of his teaching. De Volder

[1] I would like to thank Esther Howe for her assistance in proofreading this article.

[2] Not only were his ideas sought out by Leibniz, his innovative teaching was emulated by Johann Bernoulli and Christiaan Huygens held him in such high esteem as to entrust him with overseeing the publication of his posthumous works. Clerq, P.d. (1997), *At the Sign of*

was hired to teach logic at the University of Leiden, his *alma mater*, in 1670, and soon thereafter began to teach physics as well. In 1674, he traveled to England, where he met Boyle and Newton, attended meetings of the Royal Society, and witnessed several experiments, particularly air pump demonstrations. Immediately after his return, de Volder requested the Leiden curators to fund the creation of a Physics Theatre in which he would demonstrate experiments during physics lectures.[3] The curators enthusiastically agreed and in 1675 de Volder taught the first experimental physics course offered by a European university.[4] He bought a house near the main academic building and botanical gardens to house the theatre and began to furnish it with the latest equipment. He was able to secure funding amounting to one-eighth of the university's annual budget for this purpose.[5] De Volder's teaching became famous and within the next thirty years his pedagogy spread from Leiden to other institutions.

By 1705, professors at the Universities of Utrecht, Harderwijke, Franeker, and Groningen were teaching physics through experiments.[6] In the first three cases the professors were graduates from Leiden and most likely had been students of de Volder himself. At the University of Groningen, Johann Bernoulli (1667−1748) introduced the experimental approach and though he was not an alum of Leiden, we know from his January 8, 1698 letter to Leibniz that his pedagogy was directly influenced by de Volder:

> The governors have set me a new teaching task, and to this end have appropriated a certain sum to buy experimental instruments, so that, after the example of de Volder in Leiden, I shall occupy and amuse our students with mathematic-physical experiments.[7]

This experimental pedagogy spread most quickly within Dutch universities. Eventually, it made its way to other Northern European universities, however, just after 1700 there were still only a few cases: J.C. Sturm (1635−1703) at Altdorf, G.A. Hamberger (1662-1716) at Jena and Pierre Varignon (1654−1722) at the *Collège Mazarin*.[8] Interestingly, each of these cases has links to Leiden, though some are certainly more direct than others. Sturm studied at Leiden and it is likely that the spirit of observation he learned there influenced his own demonstration of experiments in his *Collegium Experimentale sive Curiosum* at the University of Altorf. Sturm began the *Collegium* in 1679 and based his experiments on those from the *Accademica del Cimento*.[9] It is in the *Collegium* at Altorf that Sturm's student, G.A. Hamberger, witnessed this new pedagogy, which he went on to use in his own teaching at Jena. The third professor, Pierre Varignon, has less clear links to Leiden. Varignon began teaching at the *Collège Mazarin* thirteen years after De Volder's first experimental course. What he knew of De Volder's activities is not clear, after all, he trained and worked in Catholic institutions, which were less likely to take the Protestant Leiden University as a model for excellence. However, it is noteworthy that he too was a longtime correspondent of Johann Bernoulli and Leibniz. It is possible that he knew of De Volder's work through them.

It is noteworthy that while much of the demonstrations taking place in the Dutch universities, Altorf, Hamberger, and Jena were based on those of the famous *Accademica del Cimento*, and while there was a rich experimental history in Italy, including some demonstrations at Italian universities before 1690, it was not until 1690 that the first university laboratory opened in Italy at the University of Bologna.[10] This is fifteen years after the founding of Leiden's Physics Theatre.

It was even longer, over 31 years, before non-Dutch universities demonstrated experiments within their *physics* courses. The first English *public* physics course included experiment and was taught by Francis Hauksbee (1666–1713) in London in 1704, but it was not until 1706 that an English *university* taught experimental physics in a course by William Whiston and Roger Cotes at Cambridge.[11] Christian Wolff continued in the tradition began in Germany by Sturm and Hamberger by teaching a course in experimental physics at Halle in 1706 and experiment did not enter the university physics classroom in Italy or Switzerland until 1737 (at Bologna and Geneva).[12]

De Volder's courses were most famous for his demonstration of the air pump, but university inventories and student notes indicate that in addition to pneumatics, he demonstrated experiments in mechanics, hydraulics, optics and magnetism. His Physical Theatre contained 64 scientific instruments, including many apparatus for his air pump, a collision machine, microscopes, fountains, a magic lantern and Magdeburg hemispheres.[13] As the lecture notes of Carolus Vinson, one of de Volder's physics students in 1676 year attests, de Volder's lectures centered on the demonstration of a variety of experiments, many taken from Boyle's *New Experiments PhysicoMechanicall Touching the Spring of the Air and its Effects* (1660).[14]

The University of Leiden

Leiden's Empirical Tradition

From its beginnings in 1575, the University of Leiden was committed to a balance of theory and practical experience.[15] William of Orange expresses this commitment in his December 1574 letter to the States of Holland and Zeeland, in which he claims that it is necessary to establish a university as:

> ...a firm support and sustenance of freedom and good legal administration of the country not only in matters of religion, but also with regard to the general welfare of the people.[16]

He goes on to say that students are to be trained

> …in both the right knowledge of God and all sorts of good, honourable, liberal arts and sciences, serving the legal administration of countries.[17]

Leiden made a point of teaching through practice in order to prepare students to meet the needs of the country.[18] The essence of this approach was providing students opportunities to observe and interact with the natural world. For example, in 1593 the university founded its famous botanical gardens and anatomy theatre and 1669 added a Chemistry Theatre, each of which became an integral part of lecture. As a medical student at Leiden, de Volder directly witnessed an additional form of teaching through observation. His professor, Franciscus Sylvius pioneered the practice of teaching medicine through clinical rounds in 1636 (a practice that continues to this day).[19] When viewed in this institutional context, de Volder's Physics Theatre, directly modeled on the Anatomy and Chemistry theatres of his institution, seem the next obvious step for a professor recently exposed to the physical experiments of the Royal Society.

Cartesianism at Leiden

De Volder was not the first to combine aspects of Descartes' philosophy with empirical pedagogy at Leiden. Sylvius provides an earlier example, one that is thought to have influenced de Volder's own abandoning of Aristotelian philosophy for that of Descartes' during his medical training.[20] This is significant, for, as Pamela Smith notes, Sylvius' approach involved:

> ...affirming observation and experiment and, at the same time, attempting to introduce mathematics into medicine….he insisted in his lecture that for natural knowledge to be truly certain, it must be *demonstrated mathematically*…[21]

Sylvius was influenced by Descartes in two important ways. As just mentioned, he too wanted certainty for the New Science and thought this was to be found in mathematical demonstration, that is, the geometrical deduction of the rationalists, though he himself did not make much progress in this regard. Second, he was influenced by Descartes' account of the passions. Sylvius held that the passions were excited by external objects and therefore connected to the senses.[22] This, and lingering concerns from his Aristotelian roots, made him worry about the reliability of information that comes to us from our senses. Further, he worried about the dangers posed to individual scientists who, through empirical observation and experiment, are immersed in the senses. For example, to protect themselves, natural philosophers must have moderate, if not chaste, bodily habits, so as to prevent the distortion of knowledge by desire.[23] Sylvius did not agree with Descartes on all things, however. For instance, he understood the body, and nature in general, in terms of chemical processes, rather than mechanical ones. What is important to us here is that through Sylvius' teaching, de Volder would have been exposed to methodologies that involve experiment and observation and at the same time, extol mathematical certainty. Further, Sylvius would have modeled for de Volder the effectiveness of teaching through empirical means, not only through anatomies, dissections, and experimentation, but through the daily clinical rounds in which students observed patients. [24] Sylvius gave de Volder an appreciation for the effectiveness of appealing to sensory knowledge in affecting their student's passions, preparing them to accept certain ideas that eventually can be proven with mathematical certainty.

Eclecticism at Leiden University

Cartesianism had an early reception at Leiden, largely as a result of the university's eclectic tradition. This tradition goes back to Franco Burgersdijk (1590-1635), who combined Aristotle with the ideas of humanists, particularly those of Pierre de la Ramée who advocated for a strong separation of the disciplines. In other words, Burgersdijk used contemporary philosophy to inform his re-interpretation of Aristotle and took it as a given that the ancient and new philosophies could be made compatible. This eclectic approach continued in the first Cartesian professors at Leiden: Adriaan Heereboord (1613-1671) and Johannes De Raey (1602-1702) who combined Cartesianism with other modern philosophies, such as those of Bacon and Gassendi, and presented these new ideas as consistent with a 'true' reading of Aristotle. This eclecticism had two important elements that encouraged a positive reception of Cartesianism in Holland. First, because the New Philosophy was not presented as a break with Aristotle, it was not considered as threatening to the university *status quo* as it was in other countries, such as France and England.[25] Second, this eclecticism, in accepting and combining the mathematical tendencies of Cartesianism and the empirical methodologies of observation and experiment, appealed to the practical orientation of the Dutch, who had a deep appreciation for the practical value of mathematics (for example, to navigation) and a growing appreciation for the value of cooperation between scientists and artisans – a trend that Wiep van Bunge says "…started to blur the distinction between practice and theory."[26] Within a few years of teaching at Leiden, de Volder adopted the eclectic approach of using logic courses to defend Descartes' philosophy by demonstrating its consistency with ancient philosophy. In doing so, he made particular use of a Burgersdijk's reading of Aristotle that called for a clear separation of the disciplines.[27] This separation was useful to the Cartesian cause in that it separated philosophy from theology. This eclecticism was appealed to when de Volder's request to the Regents suggested that the experiments in the Physical Theatre would provide a non-violent, non-partisan way to calm controversies that were then raging at the University between the Scholastic and Cartesian members of the university community. Both he and his Aristotelian colleague Wolferd Senguard (1646-1724) shared the theatre, both performing experiments from Boyle's book and yet both understanding the use of those experiments within their own epistemological framework.

De Volder's Cartesian Experimentalism

Neither Senguard or de Volder subscribed to Bacon's methodology. Both professors used experiment to verify conclusions already held, the same way they used mathematical and philosophical reasoning. They did not promote induction or try to gather new information about the world through sensory perception or experiments.[28]

De Volder's commitment to Cartesian, *a priori* methodology is found throughout his career. For example, in his earliest writing, *Consideratien over de Resolutie,* he defends Cartesian methodology. De Volder wrote the *Consideratien* with two Cartesian theology professors at Leiden. They were responding to a resolution forbidding the teaching of certain

Cartesian tenets at the University that resulted from the latest wave of Cartesian controversies.[29] The *Consideratien* was written only a year after the Physics Theatre opened, and so we can conclude that the teaching innovation of bringing experiment into the university Physics classroom was indeed by a self-identified 'Cartesian'. Further, de Volder's deep commitment to Cartesian methodology continues through his correspondence with Leibniz, which ends three years before de Volder's death, well after his thirty-year tenure of teaching students through experiments in the physics theatre. While de Volder did come to distance himself from some of Descartes' doctrines, he maintained a commitment to Cartesian methodology throughout his entire career.

So what did experiment mean to such a Cartesian? De Volder's use of experiment in the classroom was meant to awaken a desire in his students to study 'true science', that is to undertake the difficult work of deductive science. Experiment for him was not part of 'true science' itself, but an effective motivation for young boys operating mostly at the level of imagination and sensory knowledge. De Volder saw experiments as a means to prepare the student's mind for 'true science', which is a deductive understanding from first principles. Demonstrations of experiments were a way to get the students attention, to persuade them of certain possibilities through their senses and imagination, creating, if you a will, a certain disposition of belief, that would make the real work of science, reasoning from innate principles, more easily received by his young charges. Observation itself does not provide us certain metaphysical knowledge about the world, the type of knowledge that de Volder sought as a Cartesian. However, observation can provide us with a moral certainty that can give us the faith necessary to take the initiative to engage in the requisite metaphysical search for truth. This approach is importantly *pre*-Newtonian. It is true that de Volder met Newton and was later one of the first on the Continent to read the *Principia*, receiving a copy from Newton himself in 1687. However, this occurred three years before his correspondence with Leibniz, in which De Volder never asserts or defends Newtonian physics, but on the contrary, acts as an apologist for *Cartesian* physics and methodology. Further, de Volder does not mention Newton in his own writing until 1697, after twenty-two years of experimentation in the Leiden Physics Theatre. This occurs in *De rationis viribus et usu in scientis*, written while de Volder was serving as Rector of the university, and even in that work, he merely mentions Newtonianism and in no way appears to advocate it.[30]

Conclusion

In conclusion, experiment was introduced to university physics by a Dutch Cartesian, not an English Newtonian or Baconian, nor one of the members of the great Italian academies. De Volder's innovation can be understood within the context of Leiden's deep traditions of eclecticism and teaching through observation. De Volder's motivations were pedagogical (and as I argue elsewhere, political[31]). His story provides us with an interesting example of a Dutch Cartesian experimentalism, one that views observation and experiment as useful, particularly in affecting the passions, but still subservient to deduction from first principles.

ROHAULT'S *TRAITÉ DE PHYSIQUE* AND ITS NEWTONIAN RECEPTION

Mihnea DOBRE
University of Bucharest, ROMANIA
mihneadobre@yahoo.com

Abstract

Jacques Rohault (1618-1672) was one of the most important Cartesians in seventeenth-century France. He became famous in Paris, during the 1660s, when he hosted some very popular public conferences. Unlike his contemporary Cartesian fellows, Rohault was well concerned with the problem of experiment and he designed a number of instruments, which were used in his observations. The results of his experimental research were printed in the Traité de physique *(1671), which was quickly translated into Latin and published in Geneva, Amsterdam, London, and Louvain among other places.*
In this paper, I shall propose a new reading for the problem of the reception of Rohault's textbook in England. Translated and annotated by the celebrated Newtonian, Samuel Clarke, this book represents a combination of Cartesianism and Newtonianism. While Descartes' influence upon Newton's philosophy has been discussed by various scholars, the relation between Cartesianism and Newtonianism is still a topic in need of further exploration for the historians of science. Clarke's various editions of Rohault's Traité *provide a good example of the diffusion of Cartesianism at the end of the seventeenth century, making an interesting case study for the dialogue between two competing paradigms during the "scientific revolution" and the transformation of natural philosophy into physics.*

Introduction: Descartes' system of natural philosophy

In 1647, when he was preparing the French edition of the *Principia philosophiae*, Descartes wrote in the preface-letter that:

> I will here point out the fruits which I am sure can be derived from my principles. The first is the satisfaction which will be felt in using them to discover many truths which have been unknown up till now. (...) The second benefit is that the study of these principles will accustom people little by little to form better judgements about all the things they come across, and hence will make them wiser. (...) The third benefit is that the truths contained in these principles, because they are very clear and very certain, will eliminate all ground for dispute, and so will dispose people's minds to gentleness and harmony. (…) The last and greatest fruit of these principles is that they will enable those who develop them to discover many truths which I have not explained at all (AT IXb 17; CSM I 188).

One can nevertheless notice Descartes' optimism about the reception of his philosophy. In this programmatic preface to his textbook on philosophy, Descartes expresses his confidence in changing the *old* philosophy in its entirety. The second and the third benefits listed above are, in fact, direct attacks towards the traditional university teaching. They seem to suggest that Descartes' first principles are so clear that no disputes about them would be possible anymore –at least for those making a good use of their reason– which will subsequently lead to discover new things, as the first and the fourth listed fruits suggest.

As many scholars have noticed, Descartes' entire project of reforming philosophy takes the way of metaphysics. He is very specific about the right way of philosophizing, claiming in the same preface-letter that only one order should be followed. Not surprisingly, this is the same with the structure of his *Principia*, where the aim goes from metaphysics to physics, and finally to special sciences:

> Thus the whole philosophy is like a tree. The roots are metaphysics, the trunk is physics, and the branches emerging from the trunk are all the other sciences, which may be reduced to the three principal ones, namely medicine, mechanics and morals (AT IXb 14; CSM I 186).

It is interesting that Descartes acknowledges with this tree-metaphor the preparatory role of the first two parts of his book in reaching what seems to be the goal of enquiry ("to gather the fruits"), yet he does not seem to allow for possible developments in the direction of special sciences. I am referring here to his open critique addressed to Henricus Regius, a committed Cartesian from the University of Utrecht, whose *Fundamenta physices* (1646) upset Descartes.

Besides the personal note of the attack, Descartes makes also a general comment about how a philosophical work should be evaluated. He claims that readers "should not accept any opinion as true –whether in my writings or elsewhere– unless they see it to be very clearly deduced from true principles" (AT IXb 19; CSM I 189). However, what is odd with this reaction to Regius is that Descartes begins to build up something that scholars have called "Cartesian scholasticism."[1] Not only does he reduce natural philosophy to metaphysics, but he also claims that only his principles are true. Metaphysics and physics are thus linked, creating a system of intertwined principles meant to explain all phenomena.

This is quite a traditional reading of Descartes' philosophical aims and method.[2] I would not want to challenge it here, but rather to address the problem of the proposed structure of a system of natural philosophy in the context of the late seventeenth-century Cartesianism. In doing this, I shall focus on the most important Cartesian treatise on physics –*Traité de physique* (1671)– of Jacques Rohault and on its reception in England.

Jacques Rohault: Life and Works

Jacques Rohault was one of the leading seventeenth-century French Cartesians. Not only philosophically, but also socially connected to Descartes' philosophy, his views were respected and debated all over Europe. From the social point of view, Rohault was the son-in-law of Claude Clerselier, the editor of Descartes' unpublished writings.[3] He could thus become one of the focal points of the Cartesian movement in France. His house was used to host the famous "Wednesday" meetings, where Descartes' philosophy was discussed.

As far as Clair presents him, Rohault's education seems to have been a mixture of traditional university training and self-study.[4] After a first period of learning at the Jesuit college of Amiens, he moved to Paris, where he became known as a "professeur des mathématiques." With a more extensive knowledge of the sciences than any other Cartesian, Jacques Rohault has been described by Paul Mouy as working to experimentally confirm Descartes' physics.[5] Unlike other Cartesians, Rohault was also interested in the development of scientific instruments, as is confirmed by his invention of a new type of air-pump.[6]

He published little during his lifetime. A small treatise of his was however inserted into the first French edition of Descartes' *Le Monde* (1664). Clerselier, the editor of this book, presented him as "un Philosophe & Mathematicien."[7] Probably based on his public lectures and written a couple of years earlier, Rohault published a first book in 1671: it was his

---

[1] See Bohatec (1966), p. 145.

[2] Both general histories of philosophy and more specialized studies on Descartes and Cartesian philosophy are stressing the importance of metaphysics in Descartes. See for example, Mouy (1934), Copleston (1985), Garber (1992), etc.

[3] For details of the connection between Rohault and Clerselier, see Clair (1978), p. 28. A good analysis of the social roots of Rohault's experimentalism is also provided in McClaughlin (1996).

[4] See Clair (1978), pp. 23-26.

[5] Mouy (1934), p. 108: "S'efforçait de constituer, sur les bases cartésiennes, une physique expérimentale. A ses 'mercredis', tout Paris, la province, l'étranger même se pressaient pour assister aux belles expériences par lesquelles il confirmait la physique de Descartes."

[6] Mouy (1934), pp. 128-130.

[7] Cf. Thijssen-Schoute (1989), p. 269.

Traité de physique. During the same year, a second publication came out, the *Entretiens sur la philosophie*.[8] The rest of his writings, mainly on mathematics and mechanical problems, were published only after his death (1672) by Clerselier, under the title of *Œuvres posthumes* (1682).

Of particular interest for this paper is his treatise on physics, which soon after its publication became very well known in France and elsewhere. For a number of years, it was “the standing text for *Lectures* at Cambridge” (Des Chene, 2002) and “the leading textbook of its time, and it was used at the universities of Utrecht, Frankfurt, Groningen, Louvain and Leyden” (Schüller, 2001). Translated by Samuel Clarke, the book was very successful in England, where it was used in various universities. The Newtonian character of Clarke’s comments is obvious, as he makes use of Newton’s arguments and experiments to refute the Cartesian theory of matter presented by Rohault.

Before moving forward, I would like to stress that Clarke’s comments appear in various places where Rohault is presenting his theory of matter and the consequences deduced from it. Yet, Clarke leaves without comments the part of the treatise dedicated to methodological issues. As I shall argue below, this is, in my view, the main reason for this very good reception of a Cartesian textbook on physics in the context of the birth and spread of Newtonian physics, as both share a common methodology.

Cartesian Empiricism

Roger Ariew has convincingly argued for the existence of a large variety of “Cartesianisms,” pointing out both the novelty of some ideas developed by Descartes’ followers and the new methods embraced by such philosophers in their writings.[9] Thus, perhaps one of the most important –yet, puzzling– category is that of “Cartesian Empiricists” from the second half of the seventeenth century.

Jacques Rohault is the main character in this empirical movement developed within Cartesian philosophy. Starting from his opening observation in the preface to the treatise on physics –“When I came to consider Philosophy, particularly Natural Philosophy, I was very much surprised to see it so barren as not to have produced any Fruit; in so much that twenty Ages have passed, without any new Discovery made in it” (Rohault, 1987, unpaginated preface)– Rohault traces the impediments in the evolution of natural philosophy, which, in his view, was hindered by five difficulties.[10]

First, there was too much emphasis on authority. Rohault makes similar accusations as Descartes: too many people have “such a blind Submission to the Opinions of Antiquity.”[11]

Second, natural philosophy is too metaphysical. While many philosophers from the second half of the seventeenth century made similar comments –especially in the English context– the reader seems to be left wondering whether a Cartesian natural philosophy is possible, if metaphysics is eliminated from the construction of physics.

The third difficulty concerns method, as Rohault denounces the two “extremes” of natural philosophy, which either put too much emphasis on experiment or on reason, despite the fact that taken separately they cannot give us good explanations. Instead, Rohault claims that we should join them together: “it cannot but be very advantageous to mix Experiments and Arguments together.”[12]

The fourth reproach addressed to natural philosophy is once more about method. Rohault finds it strange that mathematics, as a traditional discipline, has been neglected by the Scholastics when it came to the study of natural philosophy.

---

[8] For a detailed list of Rohault’s writings and their subsequent editions, see Clair (1978), pp. 5-9. The *Traité de physique* had been translated into Latin and published in Geneva (1674), London (1682, 1702, 1708, 1710, 1713, 1718), Amsterdam (1691, 1700), Leiden (1729, 1739). In England, the second edition of the Latin translation of Rohault’s treatise (1702) was prepared by the celebrated Newtonian, Samuel Clarke (the first edition of 1682 was made by the famous Cartesian Antoine Le Grand). It was issued together with his annotations to the text, which were extended in the subsequent editions, including also four large technical footnotes written by the Jesuit Charles Morgan. While the *Traité* became more popular and its Latin edition was used as a school textbook in Cambridge and elsewhere, an English version was prepared by John Clarke, Samuel Clarke’s brother, who translated both Rohault’s text and the annotations of his brother’s Latin edition. This very influential translation was published in 1723, followed by a second edition in 1728-1729.

[9] See Ariew (2006).

[11] Rohault (1987), vol. I, unpaginated preface, p. iv.

[12] Rohault (1987), vol. I, unpaginated preface, p. ix.

The "fifth Defect" noticed by Rohault is "not in the *Method* of those who study Philosophy, but in *that* of a great many who read their works."[13] Apparently, an author cannot control this, which is precisely what Rohault criticizes here, because he seems to have feared being misinterpreted. But his critique opens another direction of his arguments from the preface, namely to create a connection with Aristotle's philosophy. He blends up Aristotle and Descartes in a new way, because he announces that the Aristotle he will use in the treatise is a rather different than the one of scholastics.

Rohault's treatise starts with a definition of physics: "we here use it to signify the Knowledge of natural Things, that is, that Knowledge which leads us to the Reasons and Causes of every Effect which Nature produces."[14] Following Descartes, he appeals to the re-evaluation of all our received knowledge: "Minds are filled with a variety of Notions," and "we must lay aside all our old Prejudices, and reject them as false."[15] By the start of the second chapter, Rohault turns to the foundations of his natural philosophy: "we know that there are *Things* really *existing* in the World; and from hence we think we know, at least in part, *what* they are."[16]

Although Rohault does not have a metaphysical foundation as Descartes, one can still find traces of Cartesian metaphysics spread all over this preliminary part of his physics. However, in order to establish his empirical approach to natural philosophy, Rohault develops first a theory of sensation. He defines the four faculties of perception, judgement, reason, and sensation, emphasizing the role of the latter. Not surprisingly, Rohault describes sensation in terms of one's capacity of being affected by an external object; but, at the same time, he presents it in alleged correspondence with the Aristotelian philosophy: "wherefore we may say with Aristotle, that all Sensation is a kind of Passion, and when we have any Sensation, whatever sort it be, we know very well what the Objects raise in us, but we don't know what they are in themselves."[17] It follows that one can expect to know only the causes of particular perceptions, but not essences, which leads to the argument for the existence of external things. Overlapping with Descartes' famous argument from the *Principia* II 1, Rohault presents his conclusion:

> Whoever acknowledges this Truth, must confess, that he has been in an Error so long as he thought that the Existence of Things without him was proved by his Senses; for all that these can do, is only to be the Occasion of knowing them; and it is chiefly from Reasoning that we are assured of their Existence.[18]

Again, he is very Cartesian, grounding the existence of bodies on our *reason*, not on our *senses*. But his explanation makes sensation (and the senses) more important, because without all the perceptions they cause, reason does not have (or, it will miss) "the occasion" to exert upon natural philosophy.

From all this, it follows what we may consider to be Rohault's method of inquiry into natural philosophy: "in order to find out what the Nature of any Thing is, we are to search for some one Particular in it, that will account for all the Effects which Experience shows us it is capable of producing."[19] Just like he argued in the preface, neither reason alone nor experience taken by itself can provide us with the needed tools for the study of natural world; instead, a permanent collaboration of the two is suggested as the right method. This insight leads to the next step in the process of enquiry:

> If that which we fix upon, to explain the particular Nature of any Thing, do not account clearly and plainly for every Property of that Thing, or if it be evidently contradicted by any one Experiment; then we are to look upon our Conjecture as false; but if it perfectly agrees with all the Properties of the Thing, then we may esteem it well grounded, and it may pass for very probable.[20]

This surprisingly Popperian program of "conjecture and refutation" entails a probabilistic account of knowledge. Indeed, Rohault draws the parallel between natural philosopher and someone decrypting a coded letter. A traditional example, which became widely used by Cartesians, starting with Descartes himself, the metaphor of the code cracker is now turned into an argument in favour of a probabilistic account of knowledge. Rohault states:

> Thus we must content our selves for the most part, to find out how Things may be; without pretending to come to a certain Knowledge and Determination of what they really are; for there may

> possibly be different Causes capable of producing the same Effect, which we have no Means of explaining.[21]

While this can be linked to Descartes' example, given at the end of the *Principia*, where two clocks with completely different mechanisms that are perfectly obscured to our senses still function in the same visible way, showing us the same time, Rohault's claim expresses something stronger.[22] Rohault deals with the epistemic status of our knowledge in physics and finds it to be always perfectible. At the same time, his words express a strong confidence in the results that have been confirmed through observation: "our Conjecture is not only to be looked upon as highly probable, but we have Reasons to believe it to be the very Truth."[23] Nevertheless, Rohault refrains from Descartes' claim that his physics is certain (recall Descartes' "more than moral certainty"). On the contrary, he makes a strong case for the permanent possibility of finding something that contradicts his conjectures. He gives the example of the new astronomical discoveries, where telescopes "have confirmed the Hypothesis of *Copernicus*." However, he warns us that even "if our Conjecture be otherwise well grounded, it does not lose its Probability, because we cannot upon the Spot explain by it a Property, which appears from some new Experiment, or which we did not before think of."[24] Hence, our knowledge in natural philosophy is perfectible and perfection is mainly achieved by the use of additional experience. Rohault's own history as experimenter testifies to this conviction.

Concluding section: the reception of the treatise in England

As mentioned above, this treatise of Cartesian physics knew its glory in the context of the birth and spread of Newtonianism. However strange that may seem to the modern reader, what I have presented in the previous section of my paper can offer a more nuanced understanding of the clash between Cartesianism and Newtonianism in the first years of the eighteenth century.

Rohault performs countless observations and engages in experiments even in those areas where theory provides a certain answer. In this sense, he is a more modern, empirical investigator than Descartes, as his experimental attempts appear to be trials performed in order to test a theory, which as a consequence is not deemed certain. Theory is then relegated to the status of a hypothesis in need of confirmation. Seen in this light, Rohault's system of philosophy becomes more consistent, but loses the certainty claimed by Descartes for Cartesian natural philosophy. Yet, when introducing the foundational elements of his physics, he is forced to deal with some of the consequences of Descartes' metaphysically rooted physics, notably with the principles of science, the essence of matter, and the role of God in the whole enterprise of creating and maintaining a law-governed universe.[25] Hence, his physics is not "metaphysically free" –despite his comments in the preface of the *Traité*.

The metaphysical certainties smuggled into Rohault's system from Descartes' *Principia* are, however, brought into a precarious situation because of Rohault's decision to subject them to (potentially falsifying) experimental testing.

Translated and annotated by the famous Newtonian, Samuel Clarke, Rohault's *Traité de physique* represents the textbook on physics for its time. Newtonian textbooks have not yet been written and Rohault fills in the missing gap with his empirically-oriented theory. However, what is important to notice here is that Clarke's footnotes are usually added whenever Rohault's starting hypotheses clashes with the Newtonian assumptions sitting at the basis of natural philosophy. Such is the nature of matter and gravity, but not the preliminary section devoted to the methodological structure of physics. In this respect, we can conclude that Rohault's system of natural philosophy makes it easier for Newtonianism to enter into the system of university teaching. Both shared the same methodological focus on experiment, which I have discussed in this paper. Of course, more can be said about the text of the treatise as well as about Clarke's remarkable footnotes, but this glimpse into the reception of Cartesianism in England is just a first step in providing a better picture of the intricate discussions about the formation of modern science.

Abstract

In the 16th century mathematics underwent in Europe deep changes whose diffusion was favoured by the invention of printing in the previous century, that changed completely the way of transmitting culture. One of the main changes was the progressive development of algebra from practical arithmetics, in which the symbolism played a relevant role.
In this paper we will analyse the circulation of symbolic language in the algebraic works of the second half of the 16th century from other countries to the Iberian Peninsula, and also this circulation in the Iberian Peninsula itself. We will give some examples to show that in some cases the use of specific symbols was due to the constrictions of typography, as Juan Pérez de Moya (ca. 1513-ca.1597) stated in his Arithmetica practica y speculativa *(1562).*
We will also analyse when symbolic language is used only as a simplification to contribute to a better understanding of the rhetoric reasoning and when it is used as a part of the symbolic reasoning, thus stepping forward from the operations with numbers to the operations with new objects of algebra. These analysis will contribute to the better understanding of the process of algebraization of mathematics in the Iberian Peninsula.

Introduction

In 16th century Europe, mathematics underwent deep changes whose diffusion was favoured by the invention in the previous century of printing, which completely changed the way of that culture was transmitted. One of the main changes was the progressive development of algebra from practical arithmetic, in which the symbolism played a relevant role.

In this paper we address the circulation of symbolic language in the algebraic works of the second half of 16th century, from other countries to Iberian Peninsula, and also this circulation in the Iberian Peninsula itself.

We give some examples to show that in some cases the use of specific symbols was due to typographical constrictions, as Juan Pérez de Moya (ca. 1513-ca.1597) stated in his *Compendio de la Regla de la Cosa, o Arte Mayor* (1558)[1].
We also show some cases where the symbolic language is used only as a simplification to contribute to a better understanding of the rhetoric reasoning, and other cases where it is used as a part of symbolic reasoning, thereby moving forward from operations with numbers to operations with new objects of algebra. This analysis will contribute to a better understanding of the process of algebraization of mathematics in the Iberian Peninsula.

In this paper we refer to the works of the following authors: Marco Aurel, Juan Pérez de Moya, Antic Roca, Pedro Núñez and Diego Pérez de Mesa. We focus on the symbolism for the unknowns as well as on the symbols to indicate the operations and on the way the authors solved the systems of equations.

Context situation

Mathematics is the least studied discipline of the 16th century in Spain. This is partly due to what is called the polemic of Spanish science: after the unjustified praises from authors like Picatoste[2], Fernández Vallín[3] and Menéndez Pelayo[4], Rey Pastor[5] demonstrated that some of this praise was unjustified and also analyzed some texts. His research is aimed at finding reasons to sadden the Spanish people or fill with them pride about their country, as well as seeking a great national figure. For this reason, Rey Pastor does not take the processes of diffusion and transmission of the knowledge into account; neither does he see scientific activity as part of a social reality. His work "Spanish Mathematicians of the 16th century" has for many years been the only source consulted on this topic, and regard for him as an authority has been a barrier to knowledge for the few researches into this subject. We must also take into account that Spain's communication with the rest of Europe almost ceased from 1557, when groups of protesters were arrested in Seville and Valladolid. One year later, King Philip II presided over the first of a series of autos-da-fe that culminated in the burning of the Spanish Protestants. This ideological repression amounted to a strict control by royal power and the Inquisition on intellectual activity, limited in principle to theology but soon spreading to other fields. These circumstances made the availability of European reference works more difficult in Spain.

Marco Aurel

The first printed text to include algebra is Luca Pacioli's (1445-1517) *Summa de arithmetica geometria proportione e proportionalita* published in Venice in 1494. The first book to be printed in the Iberian Peninsula that could be regarded as an algebraic treatise is[6]: *Despertador de ingenios. Libro Primero de Arithmetica Algebratica,* which was published in Valencia in 1552. Its author, Marco Aurel, was born in Germany and settled in Valencia, where he taught practical mathematics.

This book consists of 24 chapters. In the six first chapters the author exposes the properties of whole numbers, fractions and proportions, the rule of three, currency exchanges and progressions. From the 7th to the 12th chapter, Marco Aurel deals with square roots and cubic roots, binomials and apotomes and their square and cubic roots. In the 13th chapter he states the characters that he will subsequently use. From the 14th to the 21st, and in the 23rd and 24th chapters, he deals with the rules for solving the different types of equalities, while in the 22nd he addresses the binomials and apotomes.

Marco Aurel declares the characters he intends to use as follows:

> I want to put 10 characters in continuous proportion and call each of them by their name… the first one is called dragma or number; the second one root or thing…

---

[1] [Pérez de Moya, 1558, 4]

[2] Felipe Picatoste (Madrid 1834- Madrid 1892) is the author of *Apuntes para una biblioteca científica española del siglo XVI: estudios biográficos y bibliográficos de ciencias exactas físicas y naturales y sus inmediatas aplicaciones en dicho siglo* (1891), in which he collects the biographies of Spanish scientists who were important in their own fields during the 16th century. He wrote this book as a reaction to Echegaray's speech on his entry in the Academy of Sciences and in which he reviled the Spanish scientific tradition.

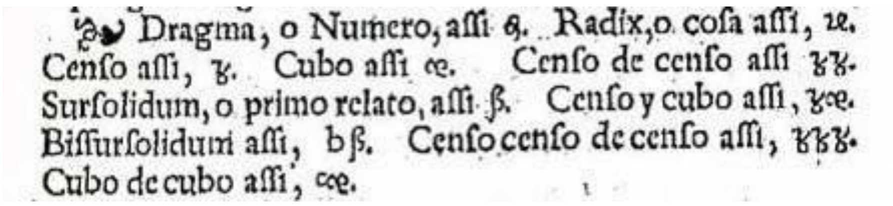
[3] Acisclo Fernández Vallín (Gijón 1825 – Madrid 1896) is the author of *Cultura científica de España en el siglo XVI*.

[4] Marcelino Menéndez Pelayo (Santander 1856 – Santander 1812), best known as a literary critic, wrote *The Spanish Science* (1876) as a claim of an existence of a scientific Spanish tradition.

[5] Julio Rey Pastor (Logroño 1888 – Buenos Aires 1962) was a mathematician who made some incursions into the history of mathematics. In his inaugural speech to the academic year at Oviedo University in 1913, he followed Echegaray's line by not giving importance to Spanish mathematicians.

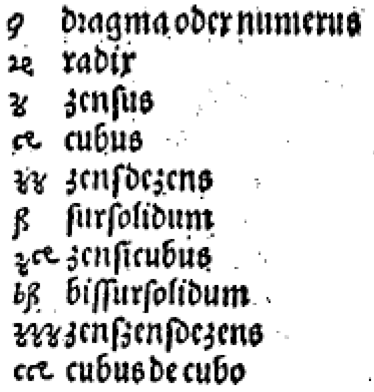
[6] This was the first algebraic treatise to appear in print, but not the first treatise in the Iberian Peninsula containing algebra, as Docampo has shown (Docampo, 2008).

> One writes the characters because they are short and to avoid writing them with all the letters …everyone can put the characters he wants…I put the following ones[7]
>
> [Marco Aurel, 1552, 69r]



Dragma, o Numero, assi ᵹ. Radix, o cosa assi, ℞. Censo assi, ʒ. Cubo assi ce. Censo de censo assi ʒʒ. Sursolidum, o primo relato, assi ß. Censo y cubo assi, ʒce. Bissursolidum assi, bß. Censo censo de censo assi, ʒʒʒ. Cubo de cubo assi, cce.

This notation shows a clear German influence, due probably to the origin of the author. In particular, the influence of Rudolff's work can be seen in the wording of several problems as well as in the notation, which Rudolff expresses as follows:



ᵹ dragma oder numerus
℞ radix
ʒ zensus
ce cubus
ʒʒ zensdezens
ß sursolidum
ʒce zensicubus
bß bissursolidum
ʒʒʒ zenszensdezens
cce cubus de cubo

[Rudolff, 1525, 174]

Aurel assigned to algebra the same names as Pacioli: *la regla de la cosa*, or *arte mayor*, or *Algebra e Almucabala*, which he translated as *restauratio e oppositio*[8] as Pacioli had translated.

To indicate addition and subtraction, he uses the signs + and –. To indicate the equality he writes the word "ygual"[9] and puts a symbol with the independent term.

4ʒ – 8℞ + 4ᵹ ygual a 36 ᵹ

[Aurel, 1552, 77r]

Rudolff uses the same symbols for addition and subtraction, and the word "gleich"[10] to indicate the equality.

Marco Aurel deals with the second quantity (systems of equations) in the 16th chapter of his algebra: «It deals with the rule of quantity and with some rules and requirements that can be done with it, and which one can refer to as a rule of second quantity» He solves 8 problems with very different wordings.

---

[7] Quiero poner 10 caracteres en una continua proporción, y nombrar a cada uno por si, por su propio nombre que le conviene... el primero se llama dragma, o numero; el segundo rayz, o cosa…
Ponense los caracteres, porque son breves, y por evitar la prolixidad de escribir tales nombres a la larga…cada uno puede poner los que a el plazeran…Yo al presente pongo los siguientes.

[8] [Aurel, 1552, 68v]

[9] equal.

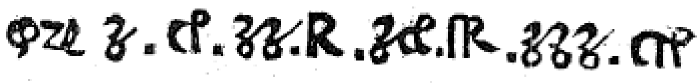
[10] equal.

The method to solve these kinds of problems is similar to the method by Luca Pacioli in his *Summa* and consists in putting the second unknown in terms of the first one, the same for the third unknown and so on. *Co*. being the first unknown, he puts *q* for the second, and when the second is expressed in terms of the first he also puts *q* for the third, and so on. This method does not allow these authors to raise the system of equations; they are obliged to work with every unknown rather than all the equations at the same time.

Juan Pérez de Moya

Aurel's book is probably one of the main sources for the most popular book written in the Iberian Peninsula during the 16th century, *Arithmetica practica y speculativa* (Salamanca, 1562) by Juan Pérez de Moya (Santisteban del Puerto, ca. 1513 - Granada, ca. 1597), which ran to 30 editions after the first publication in 1562, up to the last in 1798. In 1558 this author published the *Compendio de la Regla de la Cosa, o Arte Mayor,* which four years later was to form the seventh book of his *Arithmetica practica y speculativa.*

This work consists of nine books dealing with the properties of whole numbers, fractions, the rule of three, currency exchanges and also some practical rules of geometry. The last book is very different from the rest. It does not contain rules and is written as a dialogue between students about the importance of arithmetic, which the author wished to highlight. The rule of the thing is the seventh book, which is divided into fifteen chapters. In the second chapter Pérez de Moya provides some characters, which he says are invented for their brevity. These are:



Although Pérez de Moya gives the same characters than Aurel, he does not quote him as a source, and in the third chapter he states other characters he intends to use, because, as he says, there are no others in the print[11]. These characters are as follows: *n* for the number, *co*. for the thing, *ce*. for the census, *cce*. for the census of census, and so on, all of them belonging to the Italian tradition.

He uses no special symbol to indicate addition and subtraction, but the letters *p* and *m*, abbreviations of the Italian words "più" and "meno", which were used by Pacioli in his *Summa.* To indicate the equality he abbreviates the Spanish word "ygual" by putting "yg", and also puts a symbol with the independent term.

18. ço.m. 22. n.yg.à.10.co.p. 8. n.

[Pérez de Moya, 1562, 563]

The ninth article of the 12th chapter in the 7th book of the *Arithmética práctica y speculativa* (1562 edition) by Juan Pérez de Moya concerns the rule of second thing or quantity. He solves three problems, and the way to solve them is the same as that employed by Marco Aurel. In the 1573 *Tratado de Mathematicas* the author extended his work, particularly as regards the second quantity, which is the sixth article of the 51st chapter. An important novelty is the assignation of a letter to the third unknown, which is different from the letter assigned to the second one. In this work he quotes Cardano and Núñez thus:

> There are some other equalities which I do not include, because the wise have no need of them and beginners will not understand them. Whoever wishes to learn more should read Cardano's *Tenth Arithmetica*. And for the equalities in which the cube and the thing equal a number, they should read the end of the treatise on Algebra by doctor Pedro Nuñez, where he addresses the question with greater discretion than any of its former inventors.[12]

[11] Capítulo tercero. En el qual se declaran algunos caracteres que yo uso, por no aver en la stampa otros.

[12] Otras varias, y diversas ygualaciones ay que dexo de poner, porque para sabios no son menester, y para principiantes no se entenderan. Quien quisiere ver algo, lea el decimo d Arithmetica de Cardano. Y en las ygualaciones que el cubo y cosa, se ygyualaren a numero. Lea al doctor Pedro Nuñez, al fin del tratado de Algebra que lo trata mas discretamente, que ninguno de los que antes del lo inventaron (Pérez de Moya, 1573, 589).

Antic Roca

Antic Roca (c.1530-1580) was born in Girona and graduated in arts and philosophy in 1555 at the University of Barcelona, where in 1559 was elected a professor in arts[13].

Arithmetica (1565 edition, the first appeared in 1564) consists of 268 folios divided into two parts, each of which is made up of four books. Inside the cover of his *Arithmetica* the author says that it is a compilation of the other arithmetical works had been published up to that moment.

The first part of the book is basically a practical arithmetic, while the second deals with mercantile problems. The book belonging to this part contains the "rule of the thing".

In the XIII chapter, "On the characters that are useful for the continuous proportions and their names and significances", Antic Roca presents the characters. He says that they can be named in different ways and can also be stated in a different number.

He also notes that the quantity of characters described is not essential for the use of the rule. Nevertheless, he claims that the number of characters can be extended to infinity like the numbers themselves.

0.	1.	2	3.	4.	5.	6.	7.	8.	9.
N.	co.	ce.	cu.	cce.	r.	cecu.	rr.	ccce.	ccu.

[Roca, 1564, 258r]

He writes *mas*[14] to indicate addition and *me*[15] to indicate subtraction, and like Aurel and Pérez de Moya he puts a symbol with the independent term. Before writing this operation, he states that when the quantities have a different sign, then one must subtract the lesser from the greater, but fails to say which sign should be used. In the following operation the addition to the "*ce."* is incorrect.

3. cce. me. 8. cu. mas. 4. ce. mas. 7. co. ma. 5. n.
4. cce. me. 3. cu. me. 7. ce. mas. 5. co. me. 5. n.

7. cce. me. 11. cu. mas. 3. ce. mas. 12.

As regards the classification of the equalities, Roca says that he has decided to follow Marco Aurel and puts 4 simple and 4 compound ones.

They all correspond to those from Marco Aurel, while other expressions reproduce Marco Aurel's literally.

In the following equation we can see that Roca writes for the equality the Spanish word "yguales":

3.co.mas.2.ce.ſon yguales a.3000. nu.

[Roca, 1564, 263v]

In the fourth book of Roca's *Arithmetica*, in which he deals with the Major Art, there are no references to the rule of quantity.

---

[13] The Arts courses were preparatory studies for joining higher faculties of Theology and Medicine.

[14] *Mas* is the whole Spanish word to express the addition.

[15] *Me* is an abbreviation of the Spanish word "menos, which expresses subtraction.

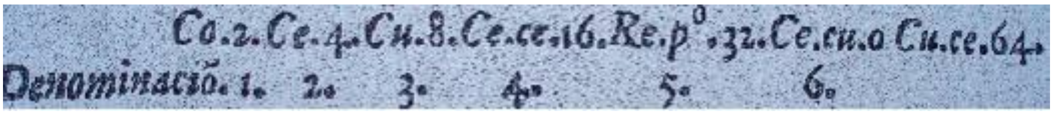
Pedro Núñez

The most remarkable mathematician in the Iberian Peninsula in the 16th century was probably the Portuguese Pedro Núñez (Alcácer do Sal, 1502- Coimbra, 1578), who studied medicine and mathematics and was a professor at the University of Salamanca as well as in Coimbra.

His book *De algebra en arithmetica y geometria,* which Núñez wrote in Portuguese during the 1530s, was not published until 1567 and appeared in Spanish. In the preface of this work, Núñez refers to the importance of Euclid's *Elements* to the foundations of algebra; he also refers to a the *Summa* from Pacioli[16] as the first printed algebra treatise, known in Spain only by a few people during the 60 years after its publication because of the obscure way in which it was written.

The algebra in Núñez's work is divided in three parts, although it does in fact consist of 5 parts, because the second one is divided into three other independent parts. In the first part, consisting of 6 chapters, Núñez gives the resolution to the first and second degree equations with one unknown. In the first chapter he deals with the purpose of algebra, its conjugations[17] and its rules. He says that the purpose of algebra is to highlight the unknown quantity and the way he will use for it is the equality. The quantities are as follows: *number*, *thing* and *census*.

He refers to them as "dignidades", and in the first chapter of the second part he gives the names for the first six quantities and explains how to obtain the others.



Co.2.Ce.4.Cu.8.Ce.ce.16.Re.p°.32.Ce.cu.o Cu.ce.64.
Denominació. 1. 2. 3. 4. 5. 6.

[Núñez, 1567, 24v]

He uses the symbol *p* to indicate addition and *m* to indicate subtraction. For the equality he writes the whole Spanish word and puts no symbol with the independent term.

20.co. p̃.7.ce. yguales a 30.co. p̃ 4.ce.m.3

[Núñez, 1567, 124r]

In the 5th and 6th chapters of the third main part, Núñez solves some problems that nowadays we would solve as systems of equations. In the 5th: *De la Practica de las Reglas de Algebra en los casos de Arithmetica,* Núñez solves 110 problems than can be solved using systems of equations, but in this chapter he makes no reference to a rule of quantity.

In the 6th chapter, Núñez deals with the rule of quantity: *About the rule of quantity simple or absolute,* and solves three problems. One of which is a problem with three unknowns; here he puts *co*. for the first and «quantity» for the second, without using any abbreviation. Using a reasoning similar to that by Aurel, Núñez puts the «quantity» in terms of the «*co*.». He works with the two first equations and also puts the third unknown in terms of the first, but without giving any name to the third unknown.

Diego Pérez de Mesa

Diego Pérez de Mesa was born in Ronda (Málaga) in 1563 and studied Arts and Theology at the University of Salamanca, where he took the courses taught by Jerónimo Muñoz (València 1520- Salamanca 1592) from his chair of astronomy and mathematics[18].

---

16 He refers to Pacioli as Fra Luca de Burgo.

17 Conjugations is the name that Núñez uses for the equations.

18 Jerónimo Muñoz was born in València, where he studied Arts. After travelling in different countries to complete his education, he held the chair of Hebrew at the University of Ancona. He returned to València where he served as professor of Hebrew and mathematics between 1563 and 1578. From 1579 he held the chair of astronomy and mathematics at Salamanca.

Pérez de Mesa wrote several mathematic works but published none of them. Manuscript 2294 at the Library of the Salamanca University is one of his works. It is a double faced 100-page treatise dated 1598. The first part deals with arithmetics and the second, which deals with algebra, begins on page 60 and consists of an introduction and 23 chapters.

The last six chapters concern the resolution of equations and systems of equations. In this manuscript Pérez de Mesa states that the algebra is called "regla de la cosa" by some authors, since the "Italians" call "cosa" the "root" or "number".

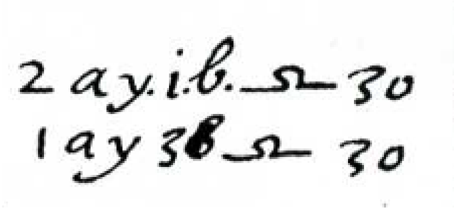
He quotes "Triputeon" when referring to the different names that algebra is called, and says that this author refers to it as "ciencia de la cuadratura". This author is Buteo, the latinized name of Jean Borrel[19], who in 1559 changed the name of algebra to the *Logistica* or, more specifically, *quadratura* and whom Pérez de Mesa also refers to in another manuscript dated 1592. He also quotes Diophantus, Pacioli, Stifel, Cardano, Tartaglia, Núñez, and Gosselin, and also refers to other "inferior" authors such as Roca and Moya.

In the twentieth chapter Pérez de Mesa studies the compound equalities, that is, the equalities that "after removing the superfluous quantities, which are those that have the character plus, and adding the tiny quantities, up to three dimensions remain". He says that it does not matter which dimensions they are, although the "writers" use the dimensions: *nº*, *£* and *q*, which can be placed in three ways.

The title of the last chapter of algebra in manuscript 2294 by Pérez de Mesa is "*de la Regla de la quantidad"* and deals with systems of equations.

For solving the systems of equations he takes no auxiliary unknown, but rather puts «a» for the first unknown, «b» for the second, and so on.

Then he sets out the system as follows:



and then solves it by linear combinations of equations. It is important to point out that the symbol for the "equality" is not introduced until the moment when he must operate with equations.

Concluding remarks

Not all the studied authors use the same symbols to indicate the unknown and its powers.

Neither Núñez nor Pérez de Mesa used any symbol to refer to the independent term. However, Aurel, Pérez de Moya and Roca did use a symbol.

The symbols used by Aurel are clearly from the German tradition and Rudolff is probably his main source.

Pérez de Moya's main source is Aurel, although he does not quote him and takes his symbolism from the Italian tradition.

Roca quotes many authors, but mainly follows Aurel.

Núñez is the most original author among these mathematicians. He says that the first book of algebra to appear in Spain was the *Summa* by *Fra Luca,* which is a rather untidy work. He also quotes Cardano and Tartaglia and critizes them for failing to be clear in their explanations.

Pérez de Mesa's main sources are probably the French authors. The way to solve systems of equations seems to be taken from Buteo, while his notation is similar to that used by Gosselin. On the first page of the manuscript by Pérez de Mesa devoted to algebra, he quotes Buteo, first calling him "Triputeon"[20] and later "Puteon". Buteo makes the system of equations

[19] French mathematician (ca. 1492-ca. 1570).

[20] Pérez de Mesa, 1598, 61.

explicit thus: [21]

3 A. 1 B. 1 C [42 | 1ª
1 A. 4 B. 1 C [32 | 2ª
1 A. 1 B. 5 C [40 | 3ª

Pérez de Mesa operates in the same way as Buteo.

In all the studied authors, the resolution of the quadratic equations is rhetorical, and although they present the symbols that they intend to use, these symbols do not modify the type of reasoning employed.

There is therefore no thread linking together the different algebras in the Iberian Peninsula during the 16th century. They otherwise draw their inspiration from different relevant works that appeared in Europe during the same period.

THE CIRCULATION OF SYMBOLIC LANGUAGE IN THE SEVENTEENTH CENTURY

Mª Rosa MASSA-ESTEVE

Abstract

This research on the symbolic language is framed within the context of a more extensive research concerning the transformations of mathematics and natural philosophy and their relationship between the fifteenth century and the seventeenth century.
The publication in 1591 of In artem analyticen isagoge *by François Viète (1540–1603) constituted an important step forward in the development of a symbolic language. As his work came to prominence at the beginning of the 17th century, other authors also began to consider the utility of symbolic language and algebraic procedures for solving all kinds of problems. Thus, symbolic language and its use in different forms became more widely disseminated, though this fact did not imply that it was generally accepted.*
In this paper, after presenting some examples of different reactions to the acceptance of symbolic language and algebraic procedures, such as those of Cavalieri, Barrow and Hobbes, I would like to analyze some examples of the connection between the transmission and reception of symbolic language and its appropriation by other scientists such as Hérigone and Mengoli or Mengoli and Leibniz. These analyses can provide new ideas for a better understanding of the algebraization of mathematics.

Introduction

This research into symbolic language is framed within the context of more extensive research into the relations between the transformations of mathematics and natural philosophy that took place from the fifteenth century to the end of the seventeenth century[1].

We analyze the relations between the following three works referred to in chronological order: *In Artem analyticen Isagoge* (1591) by François Viète (1540-1603); *Cursus Mathematicus* (1634-1637-1642) by Pierre Hérigone (1580-1643) and *Geometriae Speciosae Elementa* (1659) by Pietro Mengoli (1626/7-1686).

First of all, in order to address the circulation of symbolic language, one should consider the notation of the works under study. Certain differences exist between Hérigone's and Mengoli's signs and those used by Viète, in whose case it is

---

[1] See Massa, 2006a.

not the notation explicitly that circulates. There are in fact only a few coincidences between Hérigone's and Mengoli's notation. So the question to be posed is: In what sense can we speak about reception or appropriation between these authors? The aim of this article is to answer this question by discussing some connections between the reception of symbolic language and its singular appropriation by these authors in the seventeenth century (1591-1659).

The appropriation of Viète's algebra by Hérigone

The publication in 1591 of *In artem analyticen isagoge* by François Viète constituted an important step forward in the development of a symbolic language.

Viète used symbols to represent both known and unknown quantities, and was thus able to investigate equations in a completely general form[2]. However, if we observe Viète's equation, we can appreciate the rhetorical form. We provide one example to show how Viète writes an equation; this letter B represents the known quantity: "B in A – Aquad. Aequatur Zquad", in modern notation, $Bx - x^2 = Z^2$.

Viète showed the usefulness of algebraic procedures for analyzing and solving problems in arithmetic, geometry and trigonometry. As his work came to prominence at the beginning of the 17th century, other authors also began to consider the utility of algebraic procedures for solving all kinds of problems. Viète's work was diffused through many other algebra texts, such as the section entitled Algebra in the second volume of *Cursus Mathematicus* by Pierre Hérigone in 1634.

[2]The purpose of Viète's analytical art was to solve all kinds of problems. For more information see Viète, 1970 and 1983.

Hérigone wrote an encyclopedic textbook consisting of five volumes (six volumes in the second edition) entitled *Cursus Mathematicus, nova, brevi et clara methodo demonstratus, per notas reales & universales, Citra usum cuiuscunque idiomatis, intellectu faciles*. Published in parallel French and Latin columns arranged on the same page, the first four volumes appeared in 1634, the fifth in 1637, and a sixth in 1642 as a supplement to the second edition. The first and second volumes of *Cursus* deal with pure mathematics. The first volume contains Euclid's Elements and Data, and Apollonius's Coniques. The second volume is devoted to arithmetic and algebra. The third and fourth volumes deal with mixed mathematics, that is to say, with the mathematics required for practical geometry, military or mechanical uses, geography, and navigation. The fifth and last volume of the first edition, published in 1637, includes spherical trigonometry and music. Later, in the second edition (1642), he adds the sixth and final volume, which contains two parts dealing with algebra; it also deals with perspective and astronomy.

Algebra is a section of volume 2, which consists of 20 chapters[3]. From the description of Algebra we realize that Hérigone presents the same parts as Viète's works, and although his notation, presentation and procedures in his algebraic proofs were quite different from Viète's, Hérigone generally used Viète's statements[4].

As an example, we can see the explanation of the notation where Hérigone tries to change Viète's notation. See Figure 1.

Fig. 3.

[3] Algebra includes: 1: Several definitions and notations. 2, 3: Operations involving simple and compound algebraic expressions. 4: Operations involving ratios. 5: Proofs of several theorems. 6, 7: Rules for dealing with equations, which are the same as those in Viète's work [These rules were: the reduction of fractions to the same denominator ("isomerie"), the reduction of the coefficient of the highest degree ("parabolisme"), the depression of the degree ("hypobibasme") and the transposition of terms ("antithese")]. 8: An examination of theorems by "poristics". 9: Rules of the "rhetique" or exegetic in equations up to the second degree. 10–13: Solutions of several problems and geometric questions using proofs (determined by means of analysis). 14: Solutions of several "ambiguous" equations. 15: Solutions of problems concerning squares and cubes, referred to as Diophantus' problems. 16–19: Calculation of irrational numbers. 20: Several solutions of "affected" (negative sign) powers.

[4] On Hérigone see Massa, 2008 and 2010.

If we compare Hérigone's presentation of an identity proposition with Viète's similar identity, we can see that Viète gives rhetorical explanations and verbal descriptions, uses few symbols, employs capital letters to represent quantities, leaves no margins and writes the words "cubus", "quadratus", etc. to express powers. In contrast, Hérigone formulates all identities and properties, and even some statements, in symbols, with no rhetorical explanations or verbal descriptions. Compare Figure 2 and Figure 3.

The most important point therefore is how Hérigone appropriates Viète's proofs and transforms this rhetorical explanation into symbolic lines. In fact, Hérigone devises a new method to make the proofs. So, in the title he says: "A Course of Mathematics demonstrated by a brief and clear new method through real and universal symbols, which are easily understood without the use of any language". Hérigone also claims that he had invented a brief and intelligible new method for making proofs in the preface, which bore the dedication "Au lecteur" [To the reader]

> There is no doubt at all that the best method for teaching the sciences is that in which brevity is combined with ease. But it is not always easy to attain both, particularly in mathematics, which, as Cicero pointed out, is highly obscure. Having considered this myself, and seeing that the greatest difficulties are in the demonstrations, understanding of which depends on a knowledge of all parts of mathematics, I have devised a new method, both brief and clear, of making demonstrations, without the use of any language[5].

Indeed, Hérigone's stated aim in the *Cursus* was to introduce a symbolic language as a universal language for dealing with both pure and mixed mathematics by means of a new method. Moreover, Hérigone stressed the importance of knowing the symbols and understanding the proofs performed with this notation.

Hérigone's new method

We can distinguish three features in Hérigone's new method: the original system of notation, the axiomatic-deductive reasoning and the presentation of the propositions.

As regards the first feature, Hérigone uses an original system of notation with new symbols and abbreviations to represent algebraic expressions, numbers and signs. He provides alphabetically ordered tables of abbreviations (which he calls « explicatio notarum »); see Table 1.

He also gives tables of explanations of the citations ("explicatio citationum") at the beginning of each of the volumes that make up the Cursus; see Table 2. The citations always refer either to propositions in Euclid's Elements or to the Cursus itself. Thus, for example, "C.17.I" means "Corollarium decimae septimae primi. Corollaire de la dix-septiesme du premier".

The second feature refers to Hérigone's use of an axiomatic-deductive reasoning:

> In this method there is nothing that has not already been explained and conceded in the premises…And as each consequence depends immediately on the proposition cited, the demonstration follows from beginning to end by a continue series of legitimate, necessary and immediate consequences [6].

The third feature addresses the presentation of the propositions. Hérigone divides his propositions into separate sections: hypothesis (known and unknown quantities), explanation or requirement, proof, and conclusion. In the margin he writes the number of propositions of Euclid's Elements that he is using. Occasionally, he gives the numerical solution (for example in an equation) in a section headed "Determinatio". In geometric constructions, he provides the instructions needed to make the drawing in a paragraph named "Constructio". Hérigone claims:

---

[5] « Car on ne doute point, que la meilleure méthode d'enseigner les sciences est celle, en laquelle la brièveté se trouve conjointe avec la facilité : mais il n'est pas aisé de pouvoir obtenir l'une & l'autre, principalement aux Mathématiques, lesquelles comme témoigne Ciceron, sont grandement obscures. Ce que considérant en moi-même, & voyant que les plus grandes difficultés estoites aux démonstrations, de l'intelligence desquelles dépend la connaissance de toutes les parties des Mathématiques, j'ai inventé une nouvelle méthode de faire les démonstrations, briefe & intelligible, sans l'usage d'aucune langue. » "Nam extra controversiam est, optimam methodum tradendi scientias, esse eam, in qua brevitas perspicuitati coniungitur, sed utramque assequi hoc opus hic labor est, praesertim in Mathematis disciplinis, quae teste Cicerone, in maxima versantur difficultae. Quae cum animo perpenderem, perspectum que haberem, difficultates quae in erudito Mathematicorum pulvere plus negotijs facessunt, consistere in demonstrationibus, ex quarum intelligentia Mathematicarum disciplinarum omnis omnino pendet cognitio: excogitavi novam methodum demonstrandi brevem, & citra ullius idiomatis usum intellectu facilem." [Hérigone, 1634, I, unpaginated].

[6] En cette methode on ne dit rien qui n'aye esté expliqué & concedé aux premises... Et parce que chaque consequence depend immediatament de la proposition citée, la demonstration s'entretien depuis son commencement jusques à la conclusion, par une suite continue de consequences legitimes, necessaires & immediates »/ In hac methodo nihil adfertur, nisi fuerit in praemissis explicatum & concessum...Et quoniam singulae consequentiae ex propositionibus allegatis immediate pendent, demonstratio ab initio ad finem, serie continua, legitimaru, necessariarum que consecutionum immediatarum. Hérigone, 1634, I, *Ad Lectorem*, To the reader.

> The distinction of the proposition in its members, that is, the part in which the hypothesis is advanced, the explanation of the requirement, the construction or preparation and the demonstration, likewise relieves the memory and makes it very helpful for understanding the demonstration[7].

Hérigone's method in the demonstrations

Hérigone's originality resides not only in the explicit explanation of axiomatic-deductive reasoning, but also for using syllogisms, because in the demonstrations one can find in one symbolic line the major premise and the conclusion, using the former symbolic line as the minor premise. Hérigone's claims:

> The demonstration follows from beginning to end by a continue series of legitimate, necessary and immediate consequences, each one included in a short line, which can be solved by syllogisms, because in the proposition cited as well as in that which corresponds to the citation one can find all parts of the syllogism[8].

---

[7] « La distinction de la proposition en ses membres, savoir en l'hypothese, l'explication du requis, la construction, ou preparation, & la demonstration, soulage aussi la memoire, & sert grandement à l'intelligence de la demonstration. » / Praeterea distinctio propositionis in sua membra, scilicet in hypothesin, explicationem quaesiti, constructionem, vel praeparationem, & demonstrationem non parum iuvat quoque memoriam, & ad intelligendam demonstrationem multùm prodest. Hérigone, 1634, I, *Ad lectorem,* To the reader.

[8] La demonstration s'entretien depuis son commencement jusques à la conclusion, par une suite continue de consequences legitimes, necessaires & immediates, contenues chacune en une petite ligne, lesquelles se peuvent resoudre facilement en syllogismes, à cause qu'en la proposition citée, & en celle qui correspond à la citation, se trouvent toutes les parties du syllogisme: comme on peut voir en la premiere demonstration du premier livre, qui a esté reduite en syllogismes./demonstratio ab initio ad finem, serie continua, legitimarum, necessariarumque consecutionum immediatarum, singulis lineolis comprensarum aptè cohaeret: quarum unaquaeque

We analyze the demonstration of Proposition I in the first book by syllogisms and the identification of the premises in the demonstration.

At the beginning, Hérigone states: "This demonstration is made by four syllogisms, as one can perceive from the number of citations".

Then he explains all the syllogisms.

"III SYLLOGISM.

- Those things that are equal to the same are equal to each other.
- But the straight lines AC & CB are equal to the same straight line.
- Therefore the straight lines AC & CB are equal to each other"[9].

So, in the III syllogism, Hérigone writes: "I. axiom. 1. AC = BC", the major premise is the first axiom of Euclid's book I, while the minor premise is deduced from the conclusions of the first and second syllogisms: AC= AB and BC=BA, and the conclusion of this third syllogism is AC=BC. These conclusions enable the minor premise in the last syllogism to be deduced.

"IV SYLLOGISM.

- All triangles that have three equal sides are equilateral.
- But the triangle ABC has three equal sides.
- Therefore the triangle ABC is equilateral"[10].

In this case, Hérigone writes:" I. definition. 23. ABC is an equilateral triangle", the major premise is I.d.23, while the minor premise is deduced from the former conclusions AC= AB, BC=BA and AC=BC, and the conclusion of the third syllogism is that "the triangle ABC is equilateral", which concludes the demonstration.

Hérigone's originality resides not in demonstrating by syllogisms, but rather in that it is possible to identify all parts of the syllogism in symbolic lines, which transforms the demonstration by syllogisms into another one that is shorter and easier. Indeed, it is important to point out that Hérigone sought to introduce a new, briefer and more intelligible method for making demonstrations.

The influence of Hérigone's method on Mengoli's *Geometriae*

In this section we wish to show how Hérigone's method, devised for a better understanding of Mathematics, was used by Pietro Mengoli for obtaining new results in his *Geometriae* 30 years later.

Mengoli's *Geometriae Speciosae Elementa* (Bologna, 1659) is a text in pure mathematics consisting of 472 pages with six *Elementa* whose title: "Elements of Specious Geometry" already indicates the singular use of symbolic language in this work, and particularly in Geometry. Mengoli unintentionally created a new field, a "specious geometry" modeled on Viète's "specious algebra", since he worked with "specious" language, that is to say, symbols used to represent not just numbers, but also values of any abstract magnitudes. He deals with limits, logarithms and quadratures[11].

In the introductory letter to Fernando Riario, Mengoli reveals his sources in a reference to Viète's algebra:

> Both geometries, the old form as found in Archimedes, and the new form of indivisibles given by my tutor, Bonaventura Cavalieri, as well as Viète's algebra, are regarded as pleasurable by the

nullo negotio in syllogismum potest converti, quòd in propositione citata, & in ea quae citationi respondet, omnes syllogismi partes reperiatur: ut videre est in prima libri primi demonstratione, quae in syllogismos est conversa [Hérigone, 1634, I, *Ad Lectorem*].

[9] III. SYLLOGISME. Les choses égales à une mesme, sont égales entr'elles. Mais les lignes droites AC & CB sont égales à une mesme ligne droite. Donc les lignes droites AC & BC sont égales entr'elles./III. SYLLOGISMUS. Quae eidem aequalia sunt, inter se sunt aequalia. Sed rectae AC & BC sunt eidem rectae aequales. Igitur rectae AC & BC sunt inter se aequales. [Hérigone, 1634, I, p. 2].

[10] IV. SYLLOGISME. Tout triangle qui a trois costez égaux, est equilateral. Mais le triangle ABC a trois costez égaux. Donc le triangle ABC est equilateral. /IV. SYLLOGISMUS. Omne triangulum habens tria latera aequalia, est aequilaterum. Sed triangulum ABC tria habet aequalia latera. Igitur triangulum ABC est aequilaterum. [Hérigone, 1634, I, p.2].

[11] On Mengoli's quadratures see Massa, 2006a and 2009a.

learned. Neither through their confusion nor through their perfect conjunction, a somewhat new form [of geometry will arise] — our own— which cannot displease anyone[12].

Mengoli also claims as a source Hérigone's algebra: "To those symbols that Viète, Hérigone, Beaugrand…"[13].

Like Hérigone, at the beginning of the Geometria and on a separate page under the title *Explicationes quarundam notarum*, he explains the basic notation he intends to use. Note that for representing the powers, Mengoli, like Hérigone, wrote the exponent on the right of the letter. See Table 3.

Explicationes quarumdam notarum.

Additio ſignificabitur, charactere crucis: vt ex *a*, & *r*, collecta ſumma, *a* + *r*.

Subtractio, charactere lineolæ: vt ex *t*, dempta *a*, relinquit differentiam, *t* — *a*.

Æqualitas, ea interpunctione ſignificabitur, qua partes principes periodi ſolent diſtingui. vt quod *a* + *r*, eſt æqualis ipſi *t*,

a + *r* : *t*.

Ratio ſignificabitur interpunctione, qua maximæ partes periodi ſubdiſtinguuntur; ſcilicet puncto, & commate. vt ratio *a* ad *r*, ſcribendo,

a ; *r*.

Itaque proportio *a* ad *r*, ſicut *a*2 ad *ar*, ſignificabitur, ſcribendo,

a ; *r* : *a*2 ; *ar*.

Et compoſita ratio ex rationibus. velut ex *u* ad *a*2, & *u* ad *r*3, compoſita *u* ad *a*2*r*3, ſcribendo,

u ; *a*2, + *u* ; *r*3 : *u* ; *a*2*r*3.

vbi comma, inter *a*2, & crucem, vtiliter diſtinguit, ad ſignificandum, non quantitatum *a*2, & *u*, ſummam *a*2 + *u*, ſed rationum.

Multiplicata quoque ratio, ſignificabitur. velut *a*3 ad *r*3, triplicata rationis *a* ad *r*, ſcribendo,

*a*3 ; *r*3 : triplicata *a*; *r*.

Table 3.

The role of symbolic language in Mengoli's *Geometriae* is both significant and original. In fact, the arithmetic manipulation of algebraic expressions helped Mengoli to obtain new results and new procedures. For instance, in the *Elementum secundum* of his *Geometriae* he invented a new way of writing and calculating finite summations of powers and products of powers. He did not give them values or wrote them using the sign + and suspension points (…), but rather created an innovative and useful symbolic construction that would allow him to calculate these summations (which he calls species), which he regarded as new algebraic expressions.

In order to compute the value of these summations Mengoli displays them in a triangular table. Indeed, throughout the book he uses triangular tables as useful algebraic tools for calculations. In the *Elementum primum*, the terms of the triangular tables are numbers and are used to obtain the development of any binomial power. In the *Elementum secundum*, the terms are summations and are used to obtain their values. Finally, in the *Elementum sextum*, the terms are geometric figures or forms and are used to obtain the quadratures of these geometric figures. It is our contention that Mengoli's originality stemmed not from the presentation of these tables but rather from his treatment of them. On the one hand, he used the combinatorial triangle and symbolic language to create other tables with algebraic expressions, clearly stating their

---

[12] Ipsae satis amabiles litterarum cultoribus visae sunt utraque Geometria, Archimedis antique, & Indivisibilium nova Bonaventura Cavallerij Praeceptoris mei, necnon & Viettae Algebra: quarum non ex confusione, aut mixione, sed coniuntis perfectionibus, nova quaedam, & propria laboris nostri species, nemini poterir displicere [Mengoli, 1659, 2-3].

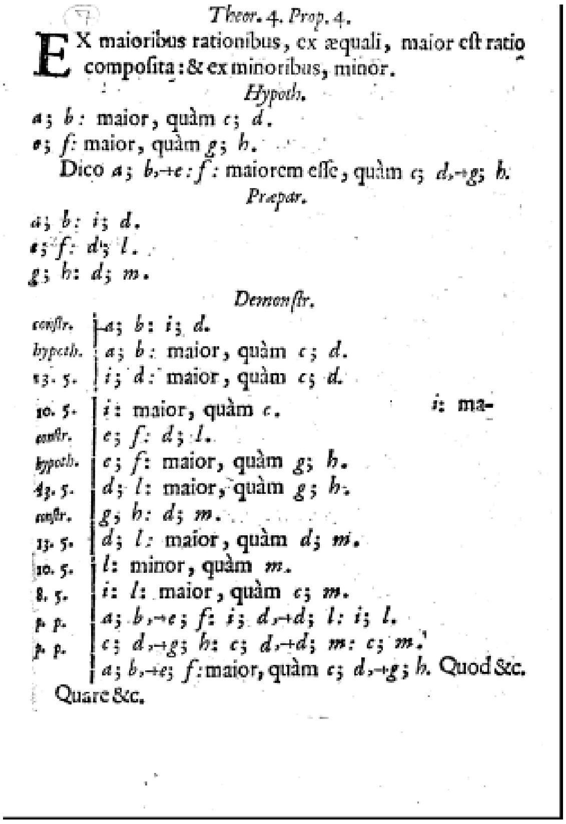
[13] Quibus characteribus à Vietta, Herigonio, Beaugrand…[Mengoli, 1659, 12].

laws of formation; on the other hand, he employed the relations between these expressions and the binomial coefficients to prove results such as the sum of the pth-powers of the first t-1 integers[14].

An important point therefore is to be found in Mengoli's triangular tables, the principal source for which is found in Hérigone's *Cursus*. In the *Elementum primum*, Mengoli defines the *Tabula proportionalium*, which he says he has constructed similarly to others in Euclid's Elements (Prop. 2 in Book 8). If you read Euclid's Elements, you will not find this triangle, but if you read Hérigone's Elements (Tome 1 of *Cursus* I) you will. We therefore conclude that Mengoli must have read about Viète's specious algebra in Hérigone's *Cursus*, and in this book found one of these principal tools, that is to say, triangular tables.

The most important relation, however, lies in the proofs and in the presentation of the propositions. Mengoli's propositions, like those by Hérigone, are divided into parts, such a "Hypothesis", "Praeparatio" and "Demonstratio". Mengoli, who was influenced by Hérigone's idea of symbolic language as a powerful tool, also absorbed his method of presenting demonstrations.

Like those by Hérigone, Mengoli's demonstrations are expressed in symbolic language with logical statements consisting of a few lines. We can identify the syllogisms in the lines of this proposition: See Figure 4.



Theor. 4. Prop. 4.

EX maioribus rationibus, ex æquali, maior est ratio composita: & ex minoribus, minor.

Hypoth.

a; *b*: maior, quàm *c*; *d*.

Fig. 4.

The circulation of ideas on symbolic language

Finally, we provide an example of the transformation of the concepts as a result of this circulation of symbolic language in the work of these three authors.

[14] In fact, the formulae for sums of squares, cubes, and higher powers of integers were crucial to the development of integration in the 17th century. Mengoli arrived at these results independently of Fermat [1891-1922] and Pascal [1954], by using symbolic language to express the summations, which enabled him to achieve a certain level of generalisation. Like Fermat and Pascal, he found a rule in which the value of the sum of the *p*th powers is obtained. However, in addition to stating the rule, Mengoli also proved it and used it to perform these values expressing all calculations in symbolic language. On Mengoli's summations, see Massa, 1997.

According to Serfati (2010, p. 108-109), the symbolic representation of the “given” was a major innovation in the late sixteenth century. In 1591, Viète introduced the letter B for the known, namely the “given”; although fixed; its value can be arbitrarily selected. One may then speak about a quantity being arbitrary but fixed. In 1634, Hérigone clearly realized and explained this advantage.

Let us show Hérigone’s view of the status of the letter “given”:

> Specious algebra is so-named from letters of the alphabet which have no particular meaning, either as discrete quantities, which are numbers, or as continuous quantities, except what one attributes to them. For example, if we attribute a value of 12 to the letter B, the reasoning applied to this letter B, without thinking of the number 12, applies to any other number, such as 15, 20, etc., and thus the letter B will represent these numbers as a kind, not as individuals or particulars. This must also be understood for continuous quantities, whether they be lines, surfaces or any other quantities one wishes. By means of these letters, one can discover universal theorems for both continuous and discrete quantities[15].

Thirty years later, Mengoli’s introduced a new concept: the determinable indeterminate quantities. Mengoli’s idea is that letters could represent not only given numbers or unknown quantities, but variables as well: that is, determinable [but] indeterminate quantities. The summations that he obtains are indeterminate numbers, but they are determinate when we know the value of t. Mengoli claims:

> When I write O.a.,...you have the summation [massa] of all the abscissae: but what value this summation is you do not yet know if I do not write what number the summation is. But if I assign O.a. to the summation of the number t, you do not know either how much it is if at the same time I do not assign the value of the letter t[16].

By assigning different values to t, Mengoli explicitly introduces the concept of the “variable”, a notion that was quite new at the time. To clarify this idea, Mengoli adds:

> But when I allow you to fix a value for the letter t, and you, using this license, say that t is equal to 5, immediately you will accurately assign O.a. equal to 10, t^2 equal to 25, t^3 equal to 125, and O.r. equal to 10, and if the letters t are determinate, the quantities O.a., O.r. , t^2 , t^3 , will be determinate. Thus, before you have used the license given, you actually had O.a., O.r. , t^2 , t^3 ,[which are] determinable [but] indeterminate quantities[17].

It should be pointed out that Mengoli uses “specious” language both as a means of expression and as an analytic tool. Therefore, Mengoli applies his idea of “variable” to calculate the "quasi ratios" (nowadays, the limit) of these summations. The ratio between summations is also indeterminate, but is determinable by increasing the value of t. From this idea of quasi ratio, he constructs the theory of “quasi proportions” taking the Euclidean theory of proportions as a model, which enabled him to calculate the value of the limits of these summations. This theory constitutes an essential episode in the use of the infinite and would prove to be a very successful tool in the study of Mengoli’s quadratures and logarithms.

Some remarks

Algebrization is a process that took place slowly and in a very different way in every country. We have presented an example on the perception for the letter representing the known by these authors, which in Mengoli’s hands allows him to introduce the idea of variable and the concept of limit. This provides us with a valuable example of the evolution of the understanding of symbolic language through this circulation in the seventeenth-century.

---

[15] “L’Algèbre Spécieuse se nomme ainsi des lettres de l’alphabet, qui n’ont aucune signification particulier, ny en la quantité discrète, qui soit les nombres, ny en la continue, sinon celle qu’on leur attribue. Par exemple, si on attribue à la lettre B12 pour sa valeur, le raisonnement qu’on fera avec icelle lettre B, sans considérer le nombre 12, conviendra aussi à tout autre nombre comme à 15, 20, etc & par ainsi la lettre B signifiera l’espèce des nombres & non les individus & particuliers. Ce qu’il faut aussi entendre en la quantité continue, pouvant signifier une ligne, une superficie, ou autre quantité telle qu’on voudra, par le moyen des quelles lettres on invente des théorèmes universels tant en la quantité continue que discrète.” [Hérigone, 1642, VI, 76]

[16] Cum scripsero *O.a.* habes massam ex omnibus abscissi: sed quota sic haec massa, nondum habes, nisi scripsero cuius numeri sit massa. Quod si assignavero *O.a.*, numeri *t* massam esse; neque sic habes, quota sit, nisi simul assignavero, quotus est numerus, valor litterae *t* …[Mengoli, 1659, 61].

[17] Cum verò licentiam dedero, ut quotum quemque litterae *t* valorem taxes; tuque huiusmodi usus licentia dixeris, *t* valere quinario : statim profecto assignabis & *O.a.*, valere 10 ; & *t*2, valere 25 ;& *t*3, valere 125 ;& *O.r.*, valere 10 ;& determinatae litterae *t*, determinatas esse quantitates *O.a., O.r.,t*2, *t*3. Quare data licentia antequam usus fueris, habebas profecto *O.a., O.r., t*2, *t*3, quantitates indeterminatas determinabiles [Mengoli, 1659, 61].

As regards the circulation of these ideas, it is not only important if one author or another uses the same symbols to represent quantities (powers); rather the significance of these symbols is more important for the process of reasoning in the demonstrations or for the resolution of the problems.

From the reception of Viète's statements and rhetorical demonstrations, Hérigone introduces a method consisting of a new symbolic notation and a new axiomatic-deductive reasoning for improving the understanding of Viète`s rhetorical demonstrations.

The symbolic language is expressed in short lines and can be identified by syllogisms. Moreover, in Hérigone's view is clearer and more concise than the rhetorical demonstrations in Viète's works. Hérigone wanted to diffuse Viète's analytic art introduced this new method for understanding better the results in the mathematical demonstrations. Therefore, the justification of the use of this method, which involves the symbolic language, lies on a didactical aim.

Later, Mengoli, who read (reception) Hérigone's *Cursus*, took (appropriate) his idea of a triangular table related to finding proportional numbers in Euclid's Elements, and developed this idea for constructing an original theory of quasi proportions.

Mengoli also absorbed (appropriated) Hérigone's ideas in his Geometriae, and presented his demonstrations using Hérigone's procedure, thereby enabling him to find new results.

Finally, this new method of demonstration using a universal language and logical sentences through an axiomatic-deductive reasoning is absolutely original and offers us the logical and clear structure of Hérigone's and Mengoli's thinking.

MATHEMATICS AND INSTRUMENTALIZATION AS "LINGUISTIC" TOOLS FOR THE WIDESPREAD CIRCULATION OF SCIENCE AND TECHNOLOGY

Nathalie HUYGHUES DES ETAGES
Independent researcher, Paris, FRANCE
nathalie.huyghuesdesetages@gmail.com

Abstract

It is often said that mathematics is a language, a position reflected by sentences like "the sense of a physical expression in the common language", or when we hear that this or that concept can give rise to a mathematical "translation"

The concept of mathematics as a language of the sciences is also part of an epistemological debate concerning disciplinary claims for the definition of a specific but nonetheless scientific disciplinary culture. Since Newton's Mechanics initiated the mathematization of physics, later extended to other natural sciences, the common vision of science is more or less dominated by the idea that physics constitutes the paragon of science and that, as a result, a science can reach a threshold of scientificness only when a certain degree of mathematization is achieved. These claims very often depend on the benefits or losses induced by the process of mathematization. One argument against mathematization is that it utilizes a physicalist ontology and that this ontology leads one to ignore specificity (of biological, human, linguistic phenomena, etc.) thus offering no more than an abusive reductionism. To the latter claim may be opposed the idea that mathematics is a language and that the difference between qualitative and quantitative properties therefore lies not in the properties inherent in the objects but in the property of the language. I will address this question not at the ontological level but rather by showing how "mathematization" can be viewed by comparison to natural language as the elaboration of a standardized language (from a linguistic point of view) which has favored the circulation of science and technology on a large scale. This, in turn, will lead me to some observations about the meaning of mathematization and about what kind of elaboration of a common language may be needed in order to favor an equally widespread dissemination of social sciences.

Despite episodic disciplinary claim about the relevance of theoretical linguistics to science (see for example, Nowak and al.(2002)), theoretical linguistics remains a rather esoteric subject, which few people had even heard of and even fewer would recognize as a branch of science, I assume that it will not be for you a completely new subject, so I will limit myself to those aspects of theoretical linguistics which is of interest for the purpose of this communication. I would like first to stress that linguistic properties are not identical to logical properties, a confusion which is too often a cause for major bias, in most studies involving theoretical linguistics, especially since the raise of computer sciences.

So let's say that all languages involve a process of semiosis to relate signs to a particular meaning (Saussure (1912), Peirce (1931-58)) but that mathematics, as well as other formal languages, can be used without semantics (the relation between the signs and the things they refer to), so it can be used in a variety of fields with totally different meanings which is not the case with natural language, but retaining syntactics (the relation among the signs in the sentence).

In my opinion it is this particular aspect which establishes a complete separation between the hard sciences, that is to say the ones that use mathematics, and the soft ones, which do not, especially when the use of a formal language to describe a particular process can be in and of itself a process of discovery an aspect epitomized by the so called "linguistic" turn in natural sciences, that is, science applies now to facts that can no longer be separated from their narrative, i.e. they are only known through their mathematical description.

Turning back to the meaning of mathematization in science, if we assume that science is a collective process whose aim is to understand the functioning of particular objects on the basis of objectively verifiable observation to achieve specific goals, we can identify two fundamental aspects of the production of knowledge, first the process of acquiring reliable information, second the process of transmitting information, both having to deal with the intrinsic limitations (in that respect) of the human perception system.

This is a very rudimentary statement, which is largely in debt with the Shannon (1948) and Shannon and Weaver (1949) model of a point to point communication system, obviously doesn't cover all the aspects of scientific activity but is nevertheless an illustration of the kind of fundamental questions one may ask about science.

Let's consider the first point, acquiring reliable information. I shall now introduce a distinction between seeing and observing: Observing reduces vision to something that takes place at one stationary point when the entire process of vision involves two movable eyes and a brain (Andersen, 2006). I shall not discuss here in depth the problems posed by perception. I will simply summarize the problem by saying that the perception system allows individuals to assimilate information from the environment but we do not see the world directly, but rather by means of the treatment of stimuli coming from the retina, that one can roughly describe as a membrane sensitive to light. Besides the eyes, which one can define as a biological sensor, vision also implements a complex cognitive process whose nature remains at stake in current research, taken over by specialized zones of the brain allowing the rough perception of the stimuli to give rise to objects whose status is still disputed. Furthermore we can derive different information, every time in different way, from the same stimuli, which leads to different narrative, especially when human factors or social factors are involved in the process of acquiring information.

In that respect, one could see the history of science as a process to control the intrinsic holistic, egocentric and variable character of human perception. For example, one may say that viewed from the point of view of Astronomy, Greek optics, and probably all astronomical optics, may be considered as an attempt to assure that distant natural phenomena are the same, regardless the viewing angle. It's worth mentioning that classical Greek optics, like classical Greek geometry was chiefly concerned with angles; both disciplines are condensed in Euclid's notion of a visual cone. Semiotically speaking, this means that the distance is a sign of (and for) a certain kind of relationship. The instrumental verification will consist in assuring that the measured length has not been altered by the viewing angle, and/or the materiality of the instrument, and the observer himself. (Salvemini, 1990).

With this example, we can define a scientific information as a collective artifact (Latour, 1983), produced through the implementation of a formal language related to formal procedures, in order to identify and observe specific objects.

Now we have to answer the basic question of what kind of system of communication is needed in order to convey that particular type of information. Turning back to the theory of information, if we consider the following scenario, a scientist needs to communicate an information to another one, and he wants to convey as much information as possible with minimum errors, the first problem will be encoding the information, the second transmitting the information so that the information is received correctly, and the third assuring that the encoding system guarantees a minimum of error for the decoding. Information theory is only concerned by encoding and decoding process as means to ensure that a message generated by a source can be correctly delivered to a receiver depending of the materiality of communication system, without worrying about the information itself, and how this information will be received by the receiver. (Yeung, 2002: 2). It is nevertheless a good starting point to understand how the holistic character of human perception, tied to the ambiguity of natural language, led to the standardization of procedures of identification of objects, and of description of objects. With time, the consensus about the object (its identification and description) generated a certain, shall we say "routinisation" of the procedures and terminology, which became increasingly detailed. They reveal in the form of mini sequences of events, the principles (clear, concise, etc.) and rules (instructions on the order of the elements, terminology and syntax, which state unequivocally how to state this information) in order to be able to communicate the concepts clearly.

This standardization allowed increasingly larger procedures of abstraction, allowing the transfer and the acculturation of these procedures worldwide.

* * *

I shall now make an attempt to show that "mathematization" can be viewed by comparison to natural language as the elaboration of a standardized language (from a linguistic point of view) which has favored the circulation of science and technology on a large scale.

Let us define a relation between two groups, A and B, which together speak of the referent C.

The two groups speak about the same referent but don't share the same language, so they can't communicate. They even may not know that they speak about the same referent. If the language of group A is in fact an idiolect of its own categories, it cannot be understood by group B, which has its own idiolect. On the other hand, if group A and group B have in common something of truly abstract nature, such as quantities, for example, they can communicate. But doing so, they introduce a new term into the tripartite relation which is the product D of the communication between A and B on C.

I can't discuss here in length the relationship between this very rudimentary analysis of the use of mathematics and the major theories of the semiotic field to which I'm obviously in debt (Frege, 1892a, 1892b, Odgen and Richards, 1923; Peirce, 1931-58; Morris, 1938, 1941), I will rather go further taking a more concrete example:

A group A is able to represent two key premises of the concept of exact numbers: the relation of exact equality and the successor function. A group A can represent the cardinal of large sets in an approximate way, with analog magnitude representations and a group B is able to track individuals in small sets of objects (parallel individuation system), and the two groups are able to solve some numerical problems. (Izard, 2010)

However, neither of these systems are powerful enough to deal with large exact numerical quantities (i.e. integers), but if the two groups are allowed to communicate, they can from those two systems of equivalent properties acquired separately and inferred from different sources of evidence build a more general theory of number.

This is more likely to happen when a very sophisticated language such as mathematics is used for communication.

Because of the particular property of mathematics, (ignoring semantics, while retaining syntactics), makes that the product D of the communication between A and B on C is not a passive product of the relation A B C; but an active product, which modifies the relation while introducing a sort of fourth dimension of the relation. This fourth dimension is therefore a model of reality that may be tested.

The use of mathematics for communication between scientists leads to the unity of the so-called *hard* because of this specific property of mathematics as a language that is ignoring semantics (the relation between the signs and the things they refer to) while retaining syntactics (the relation among the signs in the sentence). This is due to the fact that when a problem is formulated in a way that allows associating a mathematical structure to the narrative specific of the field, the syntactics remains the same, allowing a huge circulation of concepts between very distant fields, while giving an illusion of naturality, and universality.

The role of mathematics as the language of science is now challenged by the raise of computer sciences. The algorithmization of other disciplines is also a factor of the diffusion of explanatory models of the computer sciences into those disciplines (Tedre, 2007; Easton, 2006).

The relationship between formal language and science, and mathematics and science, especially when applied to soft sciences, is also renovated by the extraordinary development of algorithmic techniques associated, which allow the transfer of human competences to machines, while requiring new formalism, borrowed in part from quantum physics.

The relationship between formal language and science, and mathematics and science as well as the more philosophical debate of "instrumental" realism, (Hacking, 1983) since the extraordinary development of algorithmic techniques has allowed the transfer of a growing number of human abilities to machines, while requiring new formalism, borrowed in part from quantum physics. This process stresses a new set of questions related to identification, formalization, but also to transfer, because the functioning of machines is not similar to the functioning of the human brain.

We observe the reduction of the cognitive functions of the human brain to algorithmic processes. However dubious this reduction can be, and the opacity beyond the computational processes (Humphreys, 2009) that produce the artifact of a moving machine in the real world, the transfer of cognitive functions previously not directly observable to machines acting in the real world is an intriguing case of instrumental realism.

Abstract

After a period of political turbulence that marked the first half of the nineteenth century in Portugal, began in 1851 a new stage of constitutional monarchy. With the first Regeneration government was created a new ministry for infrastructural and industrial development, the so-called Ministério das Obras Públicas Comércio e Indústria*, under leadership of António Maria de Fontes Pereira de Melo (1819-1887). The purposes of this effort were a reduction of the socio-economic delay of Portugal compared to other West European countries, by modernizing the administration to achieve long-term economic and social development. That resulted in a significant increase of railways and roads, together with the construction of the first telegraph lines, and the establishment of an industrial education system in 1852. Industrial education had a strong practical emphasis in its curriculum courses highlighted by numerous cabinets and laboratories, at the time known as* auxiliary offices of education*. During several years were purchased scientific instruments to supply these cabinets and experimental laboratories. The equipments exhibited in the Museum of ISEP (School of Engineering of the Porto Polytechnic) belonged to the ancient Cabinet of Mineralogy and Cabinet of Mine Art and Metallurgy, and had been made by the European manufacturers Friedrich Krantz, Theodor Gerdorf, and Émile Deyrolle. Currently, they still are at the Krantz House (probably one of the oldest and largest rock, mineral and fossil traders) and*

the Émile Deyrolle House (related specially to Paleontology). At that time these were considered the benchmarks with regard to the educational material, available on almost all prestigious scientific institutions in Europe. The international and universal exhibitions were also an excellent way of spreading the scientific and technological advances. In short, the acquisition of this type of collection indicates the degree of scientific knowledge at the time, which allowed a country like Portugal to develop the industrial education and experimental training for graduates.

Introduction and objectives

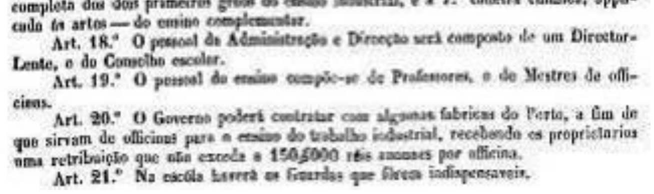
This work aims to understand foreign influences in industrial education and dissemination of science in the north of Portugal, more specifically the Industrial School of Porto in the second half of the 19th century.

In the mid-nineteenth century Portugal had only two conservatories in arts and crafts (Lisbon and Porto), without an official structure regulating industrial education. The main purpose of these conservatories was the practical instruction of all industrial processes in course on the emerging factories of the country. For this objective they had been, widely used as general storage of machinery, models, tools, drawings, descriptions and books on various arts and crafts.

After a long period of political turbulence during the first half of the 19th century in Portugal, a new stage of the constitutional monarchy began in 1851. With the first Regeneration government, a new ministry of infrastructural and industrial development was created, the so-called *Ministério das Obras Públicas, Comércio e Indústria*, under leadership of António Maria de Fontes Pereira de Melo (1819-1887). This ministry played an important role as facilitator of the national economy. This period became known as *Fontismo*; its action was marked by the intention of building bridges, roads and railways in an effort to modernize Portugal. The main idea was a significant reduction of the socio-economic delay of Portugal when compared with other European countries, by modernizing the administration to achieve long-term economic and social development. That resulted in a significant increase of railways and roads, together with the construction of the first telegraph lines and the establishment of an industrial education system in 1852.

It is in this context that arises the need to train people who could respond to the new challenges and needs of industry, where new inventions and means of production were being deployed with an increasing rhythm. As it was stated above, the industrial education was in the hands of private associations, as the case of Porto Industrial School[1] for example, which was the responsibility of the Industrial Association of Porto. In October 1852 the Industrial Association of Porto created its own industrial school, advancing to the government itself. In their statutes the need was clearly stated to instruct and educate the working classes. The major purpose would be to educate and train the working classes, teaching them to appreciate the work and providing knowledge to improve the industry.[2]

After an important decision of the government, two industrial schools were created on the main towns of Porto and Lisbon, with the aim of forming the new working class that was now emerging in our country (Decree Law December 30, 1852).



TITULO III.

Da Escola Industrial do Porto.

Art. 17.º É creado no Porto uma Escola Industrial, que comprehende a instrucção completa dos dois primeiros grãos do ensino industrial, e a 7.ª cadeira chimica, applicada ás artes — do ensino complementar.

Art. 18.º O pessoal da Administração e Direcção será composto de um Director-Lente, e do Conselho escolar.

Art. 19.º O pessoal do ensino compõe-se de Professores, e de Mestres de officinas.

Art. 20.º O Governo poderá contratar com algumas fabricas do Porto, a fim de que sirvam de officinas para o ensino do trabalho industrial, recebendo os proprietarios uma retribuição que não exceda a 150$000 réis annuaes por officina.

Art. 21.º Na escóla haverá os Guardas que forem indispensaveis.

Fig. 1: Extract of the Decree Law December 30, 1852, establishing an industrial education system in Portugal, with the creation of an Industrial School in Porto.

[1] This school had been planned for some time ago but it was only in 1852 that was achieved the law that regulated its creation and working. This law proposed to achieve a wide range of practical areas, revealing a set of activities necessary for our country.

[2] *Journal of Industrial Association of Porto*, Tome I, Porto, 1853, p. 3.

The seventeen article of the law can be translated as following:

> *"It is created in Porto an industrial school, which includes the complete instruction of the first two degrees of industrial education, and the 7th discipline –chemistry, applied to the arts– from supplementary education…"*

The government had the clear intention to adopt this effective means of teaching and, in this way, to contribute to national development. We emphasize the fact that industrial education is completely free, allowing access to education for all social classes.

Like other countries had already done, emphasis was placed on developing the national industry. To achieve this objective subsequent years were spent with significant efforts in order to introduce more new inventions, machinery and also to form their workers, teachers and leaders. Most of these people were illiterate, as most of the national population, although the official primary school existed since 1772. Thus, in 1850 it did not exist in Portugal a subsystem of industrial education. This kind of education had a strong practical emphasis in its curriculum courses, highlighted by numerous cabinets and laboratories, at the time known as auxiliary offices of education. The purchase of equipment for the classes began as early as 1853 with the mission of the government commissioner José Mauricio Vieira[3] to the city of Paris, in order to acquire certain machinery and equipment of physical chemistry. Every year were purchased diverse materials with the purpose of providing the laboratories and cabinets of the latest technology.

The industrial school and the practical education

Fig. 2: The building which housed both the Industrial School and the Polytechnic Academy, Porto.[4]

The Industrial School of Porto shared a building with the Polytechnic Academy of Porto, as well as some other spaces. We emphasize that the space that occupied the school was long considered inadequate given that the collection of

---

[3] José Mauricio Vieira was the physical preparer at the Polytechnic School of Lisbon.

[4] *Annuario da Academia Pilytecnica do Porto, Anno lectivo de 1882-1883 (sexto anno)*, Porto, Tipographia central, 1883.

practical education increased considerably every year. The installation of cabinets, laboratories and the availability of study rooms had become indispensable to the success of this type of education. Next figures confirm this situation and also show the existence of a large amount of educational material in the Chemical Laboratory and in the Physics Cabinet of the Industrial Institute of Porto.

Figs. 3 and 4: The Physics Cabinet and the Chemistry Laboratory of the Industrial Institute of Porto, in the building of the Polytechnic Academy of Porto,19th century.

Among the several specialized laboratories and cabinets of that time, we highlight now the collections of Mineralogy, Geology and Palaeontology that belonged to the ancient Cabinet of Mineralogy, later called Cabinet of Mine Art and Metallurgy. These collections are presently housed and exhibited in the Museum of ISEP (School of Engineering of The Porto Polytechnic). The main purpose of this cabinet was to form a considerable collection of minerals, ores, rocks and fossils, available to students and teachers and adequate to illustrate the overall geology and mining of the country. Since 1883, however, attention was also given to the need to incorporate didactic models in the collection of mines and metallurgy (figures 5 and 6). Nevertheless, this area only integrated with the curriculum reform of industrial education in 1864, after the establishment of Geological Surveys in Portugal. In this date was established the 7th discipline –Art of mines. This cabinet was never officially established by any decree, although it was referenced in correspondence since 1867.

Most of the collection models and specimens were purchased from European manufactures and *comptoirs* of international reference. Among them we can already highlight the excellent examples of J. Schröder[5] from Darmstad, Germany and J. Digeon[6] from Paris, France (figures 7 and 8). However, the main provider of the models of the metallurgy collection was Theodor Gersdorf.

Theodore Gersdorf (Freiberg, Saxony) was a notable constructor of models of mines and metallurgy. He constructed several manufactured examples of high quality between the years of 1880 and 1890 for the Academy of Freiberg[7] –one of the most reputable and oldest universities in Germany. He provided to the school of mines, metallurgy and mineralogy educational models specially designed for the experimental teaching of engineering. Moreover, Theodore Gersdorf provided numerous models for other schools of geology, mining and metallurgy of several European countries and the United States of America.

[7] The Academy of Mines of Freiberg was established in 1765, being one of the oldest universities in Europe and a source of knowledge and important development in the mining area.

Figs. 5 and 6: Some models belonging to the collection of mining and metallurgy of constructor Theodor Gersdorf, Germany.

Figs. 7 and 8: The manufacturers' label placed on the instruments.

In 1886, for installation of the Portuguese cabinet attached to the discipline of mining Art and metallurgy (16th discipline), a variety of new materials was commissioned. The theacher Manoel Rodrigues Miranda Junior [8], in the ordering letter of the models, wrote an interesting note which expressly refers the provider (figure 9).

This order demonstrates a perfect knowledge of what was done to the best standard of teaching material to enable the students of the school the contact with the latest technology.

At the same time and regarding the collection of Mineralogy, the largest supplier of the school cabinet was the *comptoir* "Les Fils d´Émile Deyrolle" (figure 10). It is also the first reference found in the documentation. There are numerous examples of this collection remaining in the Museum of ISEP.

Émile Deyrolle was a 19th century dealer from Paris that mainly worked with Natural History specimens and taxidermy (figure 11). For many years the *comptoir* Deyrolle specialized in Natural History publications, specimens (minerals, rocks, fossils, shells) and instruments. The fourth generation of the family also changed the company name to "Les Fils d´Émile Deyrolle" on the labels. They had taken over the business by 1896.

Fig. 11: Head of the letter sent to the Director of the Industrial School from Émile Deyrolle, 1889.

The first reference to collections purchased from the *comptoir* of Émile Deyrolle has the date of 1886 (figure 12). As usual on the procedures of the school these specimens were destined to be used as a support for the practical teaching of Zoology and Botany. As shown in this document, a receipt sent by Deyrolle (figure 13), the list of collections acquired in 1889 was very extensive and suggests significant advancements on the practical teaching.

Together with the previous *comptoir*, Friedrich Krantz was the supplier of much of the mineralogical collection of the Cabinet of Mineralogy, as if can be presently seen from the specimens housed in the Museum of ISEP. The company's founder was Dr. August Krantz (1809-1872). He developed extensive connections with main scientists and collectors, eventually becoming one of the most relevant mineral dealers in Europe. In 1850, he opened in Bonn one of the first worldwide *comptoirs* specialized in Geology and Paleontology.m Friedrich Ludwing Robert Krantz (1859-1926), August´s nephew, took over the company management in 1891; it was at this time that the *comptoir* changed its name. The label F. Krantz has been used since 1888 until today (figure 14).

The request to purchase mineral collections to the *comptoir* F. Krantz was made by a Mining professor, Artur Mendes da Costa, with the aim of equipping the cabinet, but also claiming that those samples were indispensable for teaching. According to that teacher, education had to be done in the presence of mining models and specimens that reproduced the main deposits. Most collections were purchased during the 20's of last century (figure 15).

Uebertrag:

Fig. 15: Some examples of collections acquired in 1926 for the cabinet of practical teaching: collections of minerals, fossils and pseudo morphs.

At that time this kind of collections was considered the benchmark with regard to the educational material available on almost all prestigious scientific institutions in Europe. As we can see from contemporaneous documentation, teachers had better knowledge of what was produced in educational material, indicating in their orders the exact reference to the suppliers. The international and universal exhibitions were also an excellent way of spreading scientific and technological advances. Although performed with an economic purpose, they triggered a vigorous animation in various professions.

The emergence of universal exhibitions brought a major boost in the acquisition of new resources used in industrialized countries, in industry, commerce and even agriculture. It was a unique occasion for countries to show to the world the best they did in certain areas, which also enabled the countries for the latest technology, to equip themselves for technology that would allow the development of their economies.

The economic elite was aware of the reality of our country, expressing the wish of introducing new technologies in manufacturing processes and cultivation of land. The Industrial School of Porto was often invited to participate in some of these events, showing work performed by students. The exhibitions where this Institute participated, visited, or were invited to participate spam from 1855 to 1900 (table 1).

Table 1: Exhibitions where the Institute participated, visited, or were invited to participate.

Exhibition	Date
Paris	1855
London	1862
Vienna	1873
Philadelphia	1876
Madrid	1883
Paris	1900

During these exhibitions, teachers were charged to evaluate the best of what was being done, to later apply these lessons in their classrooms, giving students up-to-date knowledge.

Concluding remarks

This study highlights the importance of collections of mines and metallurgy and their suppliers existing at the Museum of the School of Engineering (ISEP) of The Porto Polytechnic. The acquisition of this type of collections is an indicator of the scientific knowledge achieved at that time, which allowed a country like Portugal to develop the industrial education and experimental training for graduates.

The Industrial School of Porto had a strong practical component, as it was demonstrated by the existence of laboratories, cabinets and museum. In this practical component, the acquisition of new equipment, technical and scientific instruments and materials was essential to transmit knowledge and would be of great scientific and pedagogical quality, resulting also in an important component in the training of their students.

Also the international events and the universal exhibitions allowed the release of the latest scientific and technological discoveries, being visited by many teachers of that time.

Another relevant aspect is the regular contacts that the professors had with the most renowned European constructors of instruments and teaching models, showing that they know the best that was being produced in Europe concerning the experimental education materials.

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 429.

THE SCIENTIFIC LIFE OF MARIETA DA SILVEIRA

Francisca VIEGAS
Universidade de Lisboa, PORTUGAL
mfviegas@fc.ul.pt

Abstract

Marieta da Silveira (1917-2004) was born in the one of the Azores islands, and came to Lisbon where she graduated in physics and chemistry in the Faculty of Sciences.
She started research in the field of nuclear science in the Centre for Studies in Physics, where she studied the absorption of the Uranium X radiation. The hypothesis of the existence of natural radioactivity by spontaneous emission of neutrons was one of her results, published in Portugaliae Physica*. She obtained her PhD in 1945 and she continued working in the Centre until 1947, when senior researchers were expelled from the University for political reasons. The same political reasons led to a situation where she, although not expelled, was also segregated. Some years later she started working with geologists, studying radioactive minerals, doing research work where Portuguese uranium minerals, including those originated in the Portuguese colonies, are analysed. This work was more ambitious than the previous articles published in the first half of the century on the same theme –their authors were aware they were doing scientific research.*
Marieta da Siveira's research work was of great quality and some of her publications are mentioned in international documents of history of science (BAYER, R. T., Foundations of Nuclear Physics*, New York, Dover Publications Inc., 1949). Besides these research activities, she was also an outstanding teacher.*

Marieta da Silveira was born in the Azores islands in 1917. She did her secondary schooling in the Azores and, at the age of twenty, she went to Lisbon, where she started her higher education. She finished her degree in Physical and Chemical Sciences in 1941 at the Faculty of Sciences of Lisbon. At this time Marieta enrolled in a teacher training course which she abandoned because she was invited to teach at the Faculty of Sciences. Thus she started a new phase of her life in the Laboratory of Chemistry, later Department of Chemistry.

In those days faculty members were not requested to do research, and there were hardly any conditions to do so in the country. In the Faculty of Sciences there were two research centres: one in the Laboratory of Chemistry and the other in the Laboratory of Physics. Both of them dealt with radioactivity. Marieta, though she taught at the Laboratory of Chemistry, joined the Physics research centre, where she worked under the direction of Manuel Valadares and Marques da Silva, both with PhDs obtained at the Curie Laboratory, in Paris.

In 1938, Marguerite Perey had discovered the presence of the elements At and Fr in the radioactive families of Uranium and Actinium (see tables 1 and 2).

Marieta was given the task of searching for these elements in the Thorium family. She worked in this project for one year but had to abandon because the Centre could not afford a strong source of thorium in order to acquire reliable results and be confident in the conclusions. Uranium was more available so she changed her subject and dedicated herself to the study of beta and gamma emissions of the first descendants of uranium.

Due to the financial shortage, Marieta had to build herself the Geiger counters she needed and she acquired an expertise in doing so. This is evident by the fact that in 1946, A. Vigon, a lecturer from a University of Madrid, came to Lisbon to learn with Marieta. She got some interesting results which led to several publications as well as her PhD thesis entitled “Contributions to the study of the radiations of the Uranium X complex”. These publications were cited by R. Bayer in *Foundations of Nuclear Physics*, 1947:

- SILVEIRA, M. (1944) Absorption of gamma rays emitted by U I and its immediate descendants, *Portugaliae Physica*, I, 151.
- SILVEIRA, M. (1945) Natural Radioactivity by neutron emission, *Portugaliae Physica*, I, 167.
- SILVEIRA, M. (1945) On the absorption of the gamma radiation emitted by the UX complex, *Portugaliae Physica*, I, 175.

She did her PhD in 1946. While studying the beta and gamma emissions of the uranium descendants she discovered that there was also emission of neutrons. She attributed this emission to the isotope uranium Z.

In 1947, due to political reasons, the government sacked both Manuel Valadares and Marques da Silva, together with several other college professors.

Marieta continued using the measurement facilities she had helped to build to a different end: she started a collaboration with the Geology professor Torre da Assunção studying radioactive minerals, both from Portugal and from the colonies. She studied their structure using X-ray diffraction and their radiological properties. Some of this work was also published:

- MENDES, F. J.; SILVEIRA, Marieta da & VIEIRA, Glaphyra (1956). Estrutura fina dos Halos Pleocróicos observados em Rochas do Ultramar Português, *Actas do XII Congresso da Associação Portuguesa Para o Progresso das Ciências*,Tomo V, pp. 131-136 Coimbra.

- JACOBSOHN K.; SILVEIRA M. (1950). Actividade enzimática e radiações ionizantes, *Revista da Faculdade de Ciências*

After this busy period, and for reasons unknown, she had to interrupt her research work. But she did not stop: she published several notes about everyday chemistry and she translated a Russian scientific dictionary. In the late fifties, the Laboratory purchased a Perkin Elmer infrared and a Beckman V and UV spectrometer. She immediately thought of using them for research and went to Orsay where she studied these techniques. Some of the results she obtained in this field were published, in 1970, by the *J. Inorg. Nucl. Chem*. She started a study on the complexes of niobium and other group V metals, though there are no publications.

She ended her career at the age of seventy. She was an extraordinarily kind and gentle woman, an outstanding teacher, gifted to reach out to the students. All those who were lucky to know her, remember her.

She died in 2004.

Abstract

In 1922, due to the initiative of António de Carvalho Brandão, the Meteorological Service of the Navy was founded in Portugal. This was the beginning of synoptic meteorology in the country. Brandão became not only the first director of that Meteorological Service but also one of the most known Portuguese meteorologists. Four years later, at an international meteorology meeting held in Zurich, Brandão announced the decision of the Portuguese government to install a wireless telegraphy station at Azores to provide meteorological services. In 1927, Colonel Emile Delcambre, head of the French meteorological services, and Jacob Bjerknes, the famous Norwegian meteorologist, came to Portugal to meet with Portuguese authorities and discuss details concerning the Azores international station. Bjerknes came earlier to study the local weather and to get acquainted with the Portuguese meteorology services. In the last day of his visit, 23rd May, he went to the University of Coimbra with Carvalho Brandão, where he delivered a conference, later published in O Instituto*, the journal of Coimbra's academic society. He then referred to the important role Portugal might play in European weather forecast and described a project of establishing several stations in Northern Atlantic to collect transmissions from all ocean liners and communicate this information to the International Meteorological Organization, founded in 1873. The international meteorological station of Azores started to operate in 1929. The inauguration was announced at the international meteorological congress held in Copenhagen in that same year. In 1934, the Meteorological Service of the Navy was receiving daily reports from meteorological observatories in Coimbra, Oporto, Azores and 30 other stations. Of these stations, 18 were international, i.e., their data were relayed abroad from Lisbon.*

We present an episode of the history of meteorology in Europe, between the two world wars, in which Portugal played a relevant role. But we start with a brief history of meteorology in Portugal to portray its state at the beginning of the twentieth century.

The Meteorology in Portugal in the Nineteenth Century

The first meteorological observations made with a scientific purpose were made in Portugal at the beginning of the nineteenth century. Although the major concern was to establish climatic patterns of some regions and to use this information to improve public health, the hope was that the gathered data could be used to deduce major laws of atmospheric phenomena. This was the case of the observations done by Constantino Botelho de Lacerda Lobo (1754–1820), Professor of Physics at the Natural Philosophy Faculty of the University of Coimbra (UC), done at the Cabinet of Experimental Physics from 1812 to 1817. Unfortunately, these observations were of little scientific value, since they were made indoors and not at fixed hours. Also Marino Miguel Franzini (1779–1861) registered daily meteorological data in Lisbon, from 1816 to 1826 and again from 1835 to 1855. He set up a small observatory at his home, where he collected weather data, and applied statistical analysis to it (Nunes, 1988).

In 1843, Guilherme Dias Pegado (1803−85) requested the government to establish a meteorological observatory in Lisbon, as part of the Polytechnic School. The Prince Luís Observatory, the first Portuguese meteorological observatory, started to operate in October 1854. The first daily meteorological bulletin, which was delivered by the Paris Observatory from 1858 on, included Lisbon records. Storm warnings were issued, and alert signs were hoisted at the coastal stations (Ferreira, 1940). From 1865 on, the Lisbon's Observatory published a daily bulletin that provided the weather in Lisbon for the next day. Along the second half of the nineteenth century, it was a monitoring centre, gathering, in 1892, the observations of 14 national meteorological stations, seven in Spain and one in Ireland (Aires, 1892).

In Coimbra, the meteorological observations at the Physics Cabinet were resumed in 1853, being the results published in *O Instituto*, the literary and scientific journal of the academic society with the same name (Institute of Coimbra – IC), which had been founded in Coimbra in 1852 (Leonardo *et al.,* 2009). In the pages of this periodic several articles relating to meteorology appeared in its first years. Some of them stressed the urgency to establish a meteorological observatory in Coimbra in order to promote meteorological studies and to attain the same progress that was being achieved in other institutions, in the country and abroad. In 1861, the Faculty Council asked Jacinto António de Sousa (1818−80) to gather the necessary means to establish a meteorological observatory. Meteorological observations were initiated in the new observatory on 1 February 1864, while its construction continued. A telegraphic communication with the Meteorological Observatory Prince Luís was established in 1867, transmitting the morning daily observations (Lopes, 1893).

By the end of the nineteenth century, the meteorological services were centred in Lisbon. Beside the observatories of Lisbon and Coimbra, the Meteorological Observatory Princess Amelia was established in Oporto in 1888.

In the early twentieth century a *"sharp decline"* in the work done at the observatories of Coimbra, Oporto and Lisbon was visible, mainly due to internal disputes, lack of funding and staff scarcity (Leonardo *et al.,* 2011). A Technical Committee of Meteorology was appointed in 1921 to organize the meteorological services. It included, among others, Anselmo Ferraz de Carvalho and António de Carvalho Brandão. In 1914, Anselmo Ferraz de Carvalho (1878−1955) was appointed Director of the Coimbra Meteorological and Magnetic Observatory (MMO). This committee stated that there was a *"lack of meteorological stations in many regions"* and *"oceanic weather, in which we should work with other maritime countries, has long been abandoned between us"*, so that *"the actual weather service […] is fighting with many deficiencies derived from the lack of personal and material resources"* (cited in Leonardo *et al.,* 2011). The creation of a Central Institute for Meteorology was recommended, including a weather forecast and climate services. In spite of that, the scenario remained bleak.

Fig. 1: António de Carvalho Brandão.

The new methods of Weather Forecasting after the First World War

To endeavour in weather prediction, the study of meteorological phenomena within large areas by simultaneous observation of the atmospheric elements was needed. It was necessary to lay down a network of stations, spread around the country, including the Atlantic islands of Madeira and Azores, relaying surface weather observations made at periodic times. This organization was only possible with the creation of the Meteorological Services of the Navy in 1922. They were an initiative of Vice-Admiral Eduardo Augusto Neuparth (1859−1925) and the navy officer and meteorologist António de Carvalho Brandão (1878−1937). The General Marine Stewardship requested the MMO and other observatories to implement synoptic observations. Synoptic meteorology entailed the elaboration of meteorological maps, covering Western Europe, and the application of new methods to weather forecasting. Brandão played a key role in Portuguese meteorology, particularly in weather prediction, attending many international conferences on behalf of the government (e.g., London, 1921, and Utrecht, 1923).

Weather forecasting was still controversial in the scientific community at the beginning of the twentieth century (the Portuguese proverb that stated that *"if you want to lie, start predicting the weather,"* was difficult to override). Local weather forecasts done by João Carlos de Brito Capelo (1831–1901), when he was director of the Observatory Prince Luís in Lisbon, only indicated that day's probable weather. They were based in his continued attention to the state of the sky, guided by his sailor's sixth sense (Leonardo *et al*., 2011).

The 3rd Congress of the Portuguese and Spanish Associations for the Advancement of Science was held in Coimbra in 1925. Brandão presented the memoir "*The modern methods of weather forecast in Portugal".* According to Brandão, meteorology had improved in the last decades, leading to the *"formation of new hypotheses and the discovery of new laws and new methods for predicting the weather […], characterized by an intense scientific activity, looking at last to mark the actual beginning of a Meteorological Science, and thus the reasonable expectation of a scientific forecast of weather, at least in the short term".*

Modern meteorology had developed from the discovery of the laws that established the relation between atmospheric pressure and winds. The use of wireless telegraphy could open new horizons to the application of these laws to weather forecast. But the depiction of isobar lines, in spite of their relation to the winds, could not by itself allow their prediction a few hours later due to the ignorance of the evolution of the barometric field. To solve this problem, two major methods had been advanced since the First World War: the French method, based on variation nuclei and cloud systems, and the Norwegian method, based on the polar front theory.

In spite of its less scientific character, the French method provided satisfactory results in weather prediction. By tracing lines of equal barometric variation in equal time intervals (3 h, 6 h, 12 h or 24 h), also called isallobar lines, it was possible to observe nuclei of maximum variation. The movement of these nuclei showed a perfect continuity, unlike the trajectory of the depressions, and this regularity could be used to draw new isobaric lines, for the next 12 h or 24 h, and to deduce the winds and the probable state of the weather. Besides the study of the maximum variation nuclei, the French method included the depiction of cloud systems in the synoptic charts. These large clusters of clouds formed according to certain principles and moved under certain rules. There were several kinds of cloud systems, each with special characteristics and some related to unstable weather and rain. Though its reliability, the cloud system process could not be implemented in Portugal or in other countries in the oriental margin of an ocean due to the extreme difficulty in determining the cloud systems coming from the west, even considering the observations aboard ships or other oceanic stations (Brandão, 1925).

The Norwegian method, the most scientifically advanced of the time, was based on surfaces of discontinuity between adjacent air masses with different temperatures: a warm mass of air coming from lower latitudes encountered a cold mass of air originated in the polar region. Due to the Earth's rotation, the movement of the warm mass had a component to the east while the cold air mass swayed to the west. The surface of boundary between both air masses was called the polar front.

This theory was proposed by the Bergen school, in Norway, founded and headed by the physicist Vilhelm Bjerknes (1862–1951), where a meteorology service operated and applied the new method to weather prediction (Friedman, 1989). The existence of these two adjacent air masses, within a fluid, with opposite directions of displacement tended to the formation of whirls by a process where a tongue of one of the masses was projected inside the other. This was the inception of a mid-latitude cyclonic event. The north extremity of the tongue of warm air was the centre of a barometric depression known as warm sector. In the northern hemisphere, the air moved around this depression, counter clockwise, and there was also an upward movement of the air mass within the warm sector that would give place to condensation and rainfall (Figure 2).

With the further movement to the east of the tongue of warm air, the warm sector would become bordered by two surfaces of discontinuity: a warm front ahead, moving slowly as the warm air mass is climbing over the colder air mass; and a cold front in the back, moving faster (Figure 3). Hence, the warm sector gradually decreases in width while the warm air rises in altitude, giving rise to an occlusion when this sector has vanished completely from the surface. The reported evolution of a cyclonic event was deeply related with the weather below in terms of temperature, pressure and rainfall (Brandão, 1925).

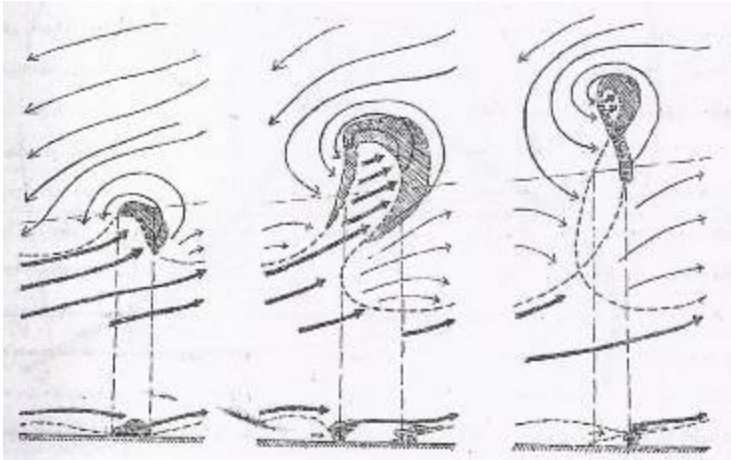

Fig. 2: Formation of a mid-latitude cyclone – front theory (Brandão, 1925).

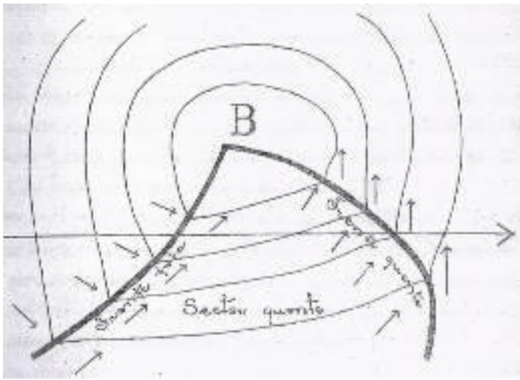

Fig. 3: Bjerknes' cyclone model (Brandão 1925).

Weather forecast by the Norwegian method relied in the regularity of the movement of the cyclonic event and its discontinuity surfaces. Therefore, the approximation of a front produced changes in pressure, temperature and wind direction. The passage of a warm front, where a retreating cold air mass was pursued by a warm current that was bound to rise (Figure 4), gave place to a temperature rise, the opposite occurring with a cold front, where a moving wedge of cold air caused the ascension of a mass of warm air (Figure 5). Both events generated the rising of hot air, which originated condensation and rain (*ibid*).

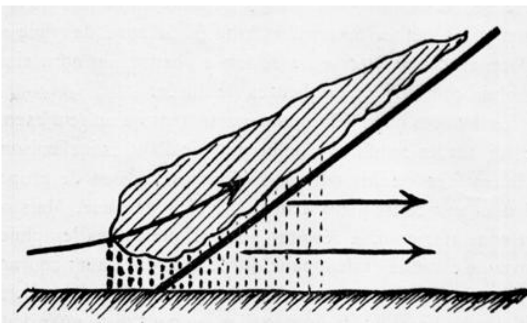

Fig. 4: Warm front (Bjerknes, 1928).

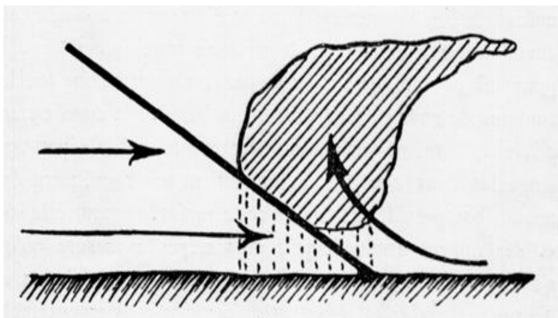

Fig. 5: Cold front (Bjerknes, 1928).

In Coimbra's congress Carvalho Brandão met António Gião (1906-69), then a young student of the University of Coimbra. In the same year, Gião departed to study at the Institute of Physics of the Globe, in Strasbourg, where he became a geophysical engineer. In 1927, Gião took an internship at Bergen School where he met Jacob Bjerknes (1897–1975), Vilhelm's son, who then headed the Norwegian National Weather Service (Gião, 1927).

Bjerknes and the International Meteorological Station of the Azores

The implementation of a worldwide weather forecasting service, based on the Norwegian method, depended on the existence of a large network of stations collecting meteorological information, especially over the North Atlantic. Also, the installation of radio transmitters aboard transatlantic liners allowing them to regularly relay meteorological data while crossing the ocean, would give additional coverage to the project. This was the issue in the meteorology international meeting which took place in Zurich in 1926. Carvalho Brandão, as chief of the Portuguese meteorological service, announced there the commitment of the Portuguese government to establish an international meteorological station at the Azores, which was prepared to receive and relay by radio meteorological data emitted by ships in the region. A committee, composed by Jacob Bjerknes and General Émile Delcambre (the director of the French meteorological services), was set up to follow this matter until its final resolution (Leonardo *et al.,* 2011).

Fig. 6: Jacob Aall Bonnevie Bjerknes (Bjerknes, 1928).

Jacob Bjerknes was a member of the group of meteorologists, led by his father, which developed the model of mid-latitude cyclones based in the front theory. In May 1927, he came to Portugal to study the local meteorology and to meet the Portuguese government to stress the urgency of the meteorological station of the Azores (Delcambre and Brandão were also present). This station would solve *"a problem that concerns the scientific bodies of Europe, in charge of the study and weather prediction"* due to the lack of observations in the Northern Atlantic.

Bjerknes was invited by Ferraz de Carvalho, on 23rd May 1927, to speak at the IC on *"Les bases scientifiques et techniques de la prévision du temps et le rôle du Portugal à ce rapport"*. He presented his polar front theory and the means to apply it to weather prediction. In his paper, published in *O Instituto*, he recalled the importance of weather forecasts for maritime countries. A system of stations relaying atmospheric data abroad by wireless telegraphy, scattered across the globe, was essential. In a map, Bjerknes showed the location of weather stations that, according to the international plan, would receive information from vessels with radio emitters that were regularly transmitting meteorological data within the areas covered by each station. These stations would relay the information, three or four times a day at established international hours, to the European Meteorological Services. The region covered by the Azores, Madeira and the Portuguese coast encompassed a large ocean surface. The others were the Bermudas and, further north, Newfoundland, Greenland and Iceland (Bjerknes, 1928).

Although a Meteorological Service had been established in Azores in 1901 (with four observatories) (Tavares, 2009), the International Meteorological Station of Azores, in Faial Island, only became operational in 1929. Delcambre, in the International Meteorological Congress of Copenhagen which took place in that same year, pointed out the highest service which was being provided to science by Portugal. He said it was one of the most important events contributing to the progress of meteorology in the century, adding that it was the beginning of a new era: indeed, the Azores station was the completion of a vast international network, a base to aero-transatlantic navigation. In Copenhagen the major collective emitters for the northern hemisphere were created. They should incorporate and link together emissions received from several international weather stations (Morna, 1935). The Azores' Station information was included in the collective emissions from Western Europe.

The Portuguese Meteorological Services before the Second World War

From its creation until 1946, the Meteorological Service of the Navy (MSN) was responsible for weather forecasting. In 1934, the MSN was receiving daily reports from meteorological observatories in Coimbra, Oporto, Azores and 30 other stations (26 in the continent, 2 in Madeira and Azores and 2 in Green Cape). Of these, 18 were international, i.e., their data were relayed abroad from Lisbon. More than 80% of the words used in the Navy radiotelegraphic services were taken by the meteorological services. The service produced daily meteorological maps of Europe and the Oriental Atlantic (Figure 7) along with weather forecasts (Morna, 1935).

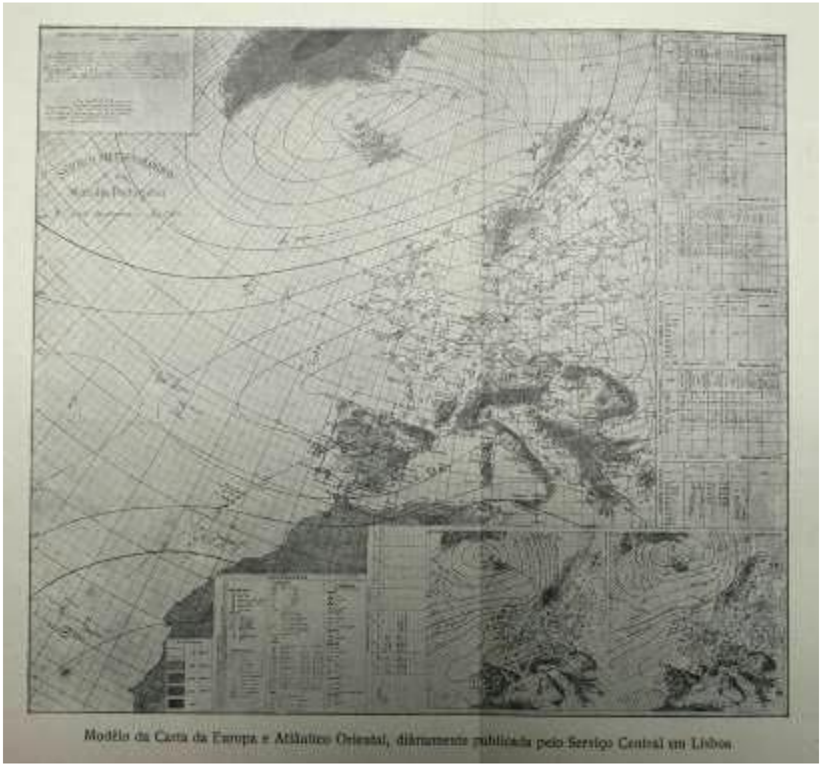

Fig. 7: Meteorological map of Europe and Eastern Atlantic (Morna, 1935).

The efficiency of the weather prediction service in the Atlantic was tested by the preparation of the flight across the Atlantic of the airplane ESA (*Espírito de Santo Agostinho*), from Lisbon to New York, in 1931 (Morna, 1934). The help of the MSN to decide the best route was requested by the flight crew, composed of Costa Veiga, Christhien Johnson and Willy Rody (Figure 8). This endeavour ended in a sea landing due to lack of fuel, the meteorological services being essential to rescue the pilots. According to the Spanish journal ABC, in 16 September 1931, *"the atmospheric conditions of the Atlantic are still being those predicted by the Meteorological Service of the Navy ministry. Everything seems to indicate that the aviators had displaced themselves from the route that those services delineated"*.

Despite the successes of the weather services, meteorological science was scarcely studied in Portugal. An exception was António Gião, one of the most renowned Portuguese meteorologists. Gião published *La Mechanique Différentielle des Fronts e du Champ isallobarique* (1930), a book containing forewords from Delcambre and Jacob Bjerknes. He had proposed to the National Board of Education in Portugal the creation of an Institute of Atmosphere Mechanics. The board counter offered him a scholarship, which he refused.

Brandão resumed the state of the art of meteorology science in an article entitled *Importance of General Movements in the study of the atmosphere*, published in 1931 in *A Terra,* a Portuguese journal on geophysics. He addressed the Norwegian method, stating that it *"did not lead in turn to a defined method of prediction, but merely to the acquisition of scientific knowledge on certain atmospheric phenomena in the dynamic point of view, hitherto almost unexplored […], the famous Norwegian method is but one method of analysis and diagnosis of meteorological situations […] [in] the regions where the discontinuities of meteorological elements occur"*. Regarding Gião's studies, *"however it should represent a major advance in meteorological science, still Gião's method cannot, naturally, give us a definitive solution to the problem of prediction"* (Brandão, 1931).

Fig. 8: The pilots of ESA after their rescue.

In 1933, the Society of Meteorology and Geophysics of Portugal (SMGP) was founded in Coimbra, being Anselmo de Carvalho its Honorary Chairman. Albeit its ambitious goals and the major figures involved, it did not receive the required government support to become permanent and was extinguished after a few years (Leonardo *et al.,* 2011).

By then, various meteorological services were scattered by several state and government departments, like the Civil Aviation Secretariat, the Observatory Prince Luís and the Meteorological Service of the Azores, under the ministry of Education; Meteorological Services of the Navy, supervised by the ministry of the Navy; the General Directorate of the Agricultural Services, under the ministry of Economy; and similar services in the ministries of the Army and of the Colonies.

* * *

Brandão, who always sought to implement scientific meteorology, established contacts with major European figures like Delcambre, Bjerknes and Shaw. His great ambition was the creation of a National Institute of Meteorology. According to Gião *"His project and initiatives collided with a wall of envy, with the rivalry of pulverized services in multiple ministries, and was with the bitterness of not being able to do anything that he passed away prematurely."* A major difficulty was the systematic lack of financial resources and qualified personnel. An example was the inability to meet Gião's challenge to create an institute devoted to the study of the atmosphere.

International pressure for advancing meteorology in Portugal has always been present, especially from the days when the gathered observations, particularly in the Atlantic islands, became essential to the development of the global effort of weather forecasting (Leonardo *et al.*, 2011).

Only in 29th August 1946, after the war's end, the creation of the National Meteorological Service was established, integrating all the meteorological services that were dispersed among different institutions and observatories.

Abstract

The need of refrigeration in the laboratory is not a new idea, and this paper intends to make a tour through its history in the 19th century, where one of the first attempts to make things cooler was created by the Carré brothers. The aim is to explore the types of Carré Apparatus and the techniques used in it, and to study their evolution and improvement. This work will focus mostly in the instrument's collection of the Museum of Science of the University of Lisbon, which owns several exemplars of the Carré Apparatus as well as improved versions of it. Our approach tries to put these objects back in their real place in the 19th century lab work, corroborating equipment with archival sources by establishing links between equipment and photographs, reports, curricula, chemistry compendia, textbooks written by the professors, where certain experimental settings are described and depicted, invoices and other administration papers, e.g. the 1854 inventory, among other archival and bibliographical sources. The 19th century 'Laboratorio Chimico' *of the Polytechnic School (1837-1911), integrated in the Museum of Science of the University of Lisbon suffered a restoration and a musealization work (1998-2007) as well as a part of the museum's heritage, where a Ferdinand Carré's apparatus is included. This historical space and the pertaining collection allows us to go back to the 19th century scientific practice at the Lisbon Polytechnic School and breathe its atmosphere in a golden period.*

Artificial production of ice

In the 16th century, the discovery of chemical refrigeration was one of the first steps toward artificial means of refrigeration. The first attempt to artificial production of ice was implemented by Lahire in 1685: he produced ice by wrapping wet ammonia salt and a jar full of water, already cooled (Figuier; 1873). The first machines used in the mechanical production of cold were constructed on the principle of the vacuum machine, wherein the vacuum –which was obtained mechanically– permitted the refrigerant to boil at a sufficiently low temperature to secure the results desired. These machines included that of William Cullen (1710-1790), used in 1755 for producing ice using water under high vacuum; the optician and scientific instrument maker Edward Nairne (1726 – 1806) recognized that water vapour is rapidly absorbed if he put a container with water near a pot with sulphuric acid, both closed, inside a pneumatic machine bellflower. Later in 1811, the physicist John Leslie (1766 –1832) obtained water boiling at a low temperature (Leslie; 1813).

Ferdinand Carré's apparatus

In 1856, the French engineer, Ferdinand Philippe Edouard Carré (1824–1900) developed his first refrigeration apparatus using sulphuric ether, with the inconvenience that ether is highly inflammable. Later in 1859, Ferdinand Carré made the first ammonia / water refrigeration machine. The Carré absorption cycle used in this apparatus was an outgrowth of the observation by Michael Faraday (1791–1867) in 1823, which noticed the cooling properties of ammonia closed in a bent glass tube. Ferdinand replaced the ether by ammoniac because of its stability, low boiling point (44º C) and its affinity with water. This absorption machine (figure 1) was patented in France in 1859 and in the U.S.A. in 1860 (Figuier; 1873). The abstraction of heat is made by evaporation of a separate refrigerating agent of volatile nature under the direct action of heat, which agent again enters into solution with a liquid. This is termed the "absorption system" (Greene; 1916). When a body changes its state, a certain amount of energy must be absorbed by that body to bring about this changed state. The name "heat energy", or heat, is applied to this. Energy is required to change a body from the liquid state to the vapour state.

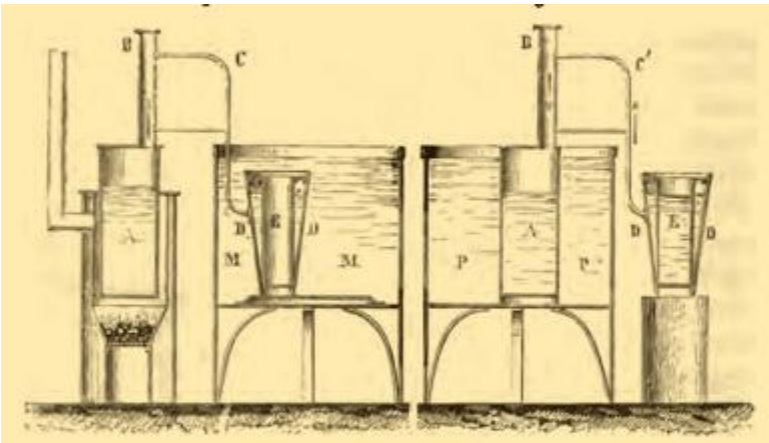

Fig. 1: Engraving representing a Ferdinand Carré's apparatus (Jamin; 1878).

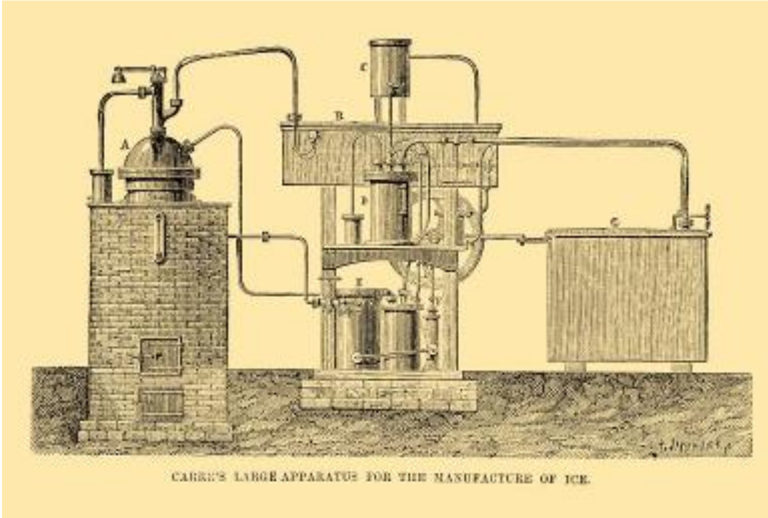
This apparatus consists in two pots hermetically closed, in communication by means of tubes. The largest (A), a cylinder, contains a concentrated ammonia solution (ammoniac gas dissolved in water), which is heated with a furnace. The small one (E), a vessel in the shape of a truncated cone having a cavity in centre, was kept in a trough with water. This refrigerating machine is furnished with a thermometer which doesn't communicate with the interior of cylinder (A).

But how does this apparatus work? The cylinder (A) contains ammoniac gas, dissolved in water. When it is heated, the gas espies from the liquid and passes into a vessel (E), after having passed through all the connecting tubes. But on arriving there it finds no exit, accumulates, and under the influence of cooling and considerable pressure, becomes liquefied. This is the moment when the generating cylinder (A) is plunged into a cold water container and consequently cooled. The gas which is liquefied in vessel (E) returns to a gaseous state, a corresponding absorption of heat accompanies this change, and the water dissolves once more the ammoniac gas and the primitive ammoniac aqueous solution formed (in A). Soon it is possible to take from the cavity a block of ice (Tissandier; 1867).

Ferdinand apparatus had great advantages: ice could thus be produced using small portions of coal; its small dimensions prevented the production of large quantities of ice at once. But it could not be made to work continuously, and could never be of much industrial value. Another apparatus (figure 2), however, had been invented by him, constructed on a much larger scale, and had successfully solved the important problem of the artificial manufacture of ice or the production of cold.

A large boiler (A) contains the solution of ammonia. The gas escapes and becomes liquefied in a reservoir (B), cooled off as it is by the water which falls from a reservoir (C). The liquid ammonia penetrates into the hollow sides of the refrigerator (G), which contains cylinders filled with the water that is to be frozen. During this time an especial arrangement allows this waste water of the boilers to penetrate, after having cooled off, into a vessel (E) connected with the cylinder (D), in which the ammonia is distilled that has been volatilized in the refrigerator. The original liquid, thus regenerated, is conveyed into the boiler by means of a pump (F). This apparatus acts with great regularity, and it is astonishing to see large blocks of ice issuing from this refrigerator, which are formed as if by magic, without any visible agent to show the secret of their formation.



CARRÉ'S LARGE APPARATUS FOR THE MANUFACTURE OF ICE.

Fig. 2: Engraving representing a Ferdinand Carré industrial apparatus (Tissandier; 1867).

In 1862 Ferdinand Carré exhibited his ice-making machine at the Universal London Exhibition, producing an output of 200 kg/h (Figuier; 1873). Its design was based on the gas-vapour system. Ferdinand's industrial apparatus had the great advantage of allowing a continuous ice production.

Edmond Carré's apparatus

In 1811 John Leslie described a laboratory method of making ice by freezing water in a saucer placed in a receiver under vacuum –the water vapour, as it boiled off under low pressure maintained in the receiver, is absorbed by sulphuric acid in another saucer (Leslie; 1813). In the case of the vaporization of a liquid under reduced pressure, the aim of this reduction is to allow the evaporation at such a low temperature that heat may be removed from surrounding objects of low temperatures. When the pressure was reduced, the boiling temperature would decrease and with the evaporation of some liquid, ice could form. Leslie improved this machine later into a pneumatic machine, under the principle that the abstraction of heat is effected by the evaporation of a portion of the liquid to be cooled, the process being assisted by an air pump (Macintire, 1928). This is known as a vacuum system.

In 1866 Edmond Carré (1833-1894), Ferdinand's brother, repeated the Leslie experiment and found that it was necessary a larger quantity of sulphuric acid for a small quantity of water. At the same year, Edmond adapted the Leslie process to a pneumatic machine and added an agitator to renew the surface of sulphuric acid and increase the surface area in contact with water vapour and thus improve the capacity of sulphuric acid to absorb it. He obtained a bigger efficiency, allowing the production of greater quantities of ice (Jamin; 1878). Water is placed in a bottle that adapts to a tube, which will give a bath of sulphuric acid, continually being shaken with an agitator (figure 3).

This apparatus consists of a pneumatic pump (P) and a large tank (R). The sulphuric acid is introduced in the tank (R), which is in communication with the pneumatic pump (P) through the tube (b) and in communication either with the bottle of water through the tube (h) and the tap (r). The lever (M), which gives movement to the stem of the piston of the pneumatic pump, moves through the stalk (t) an agitator, which constantly renews the surface of the acid.

The Edmond's apparatus great advantage (Vidal; 1893) was that in three minutes the water temperature decreases to the freezing point and ice is produced.

Refrigeration apparatus in the Polytechnic School of Lisbon

The Polytechnic School of Lisbon was a landmark in Portugal because it was one of the few schools where chemistry was taught. It was founded in 1837 in order to prepare students for the Army and Navy schools, while offering access to higher science education for students of other professions, medicine and pharmacy. In accordance with the foundational document, the School was to be provided with a Library, an Astronomical Observatory, a Cabinet of Physics, a Chemical Laboratory, a Natural History Cabinet, a Botanical Garden and other common facilities. The disciplines were organized and taught in five courses. The *6ª Cadeira* –denominated 'General Chemistry and Principles of its Applications to the manufactures'– was usually lectured in the second year of most of the courses (Elvas; 2009). An additional discipline was created in 1859: Chemical Analysis and Organic Chemistry.

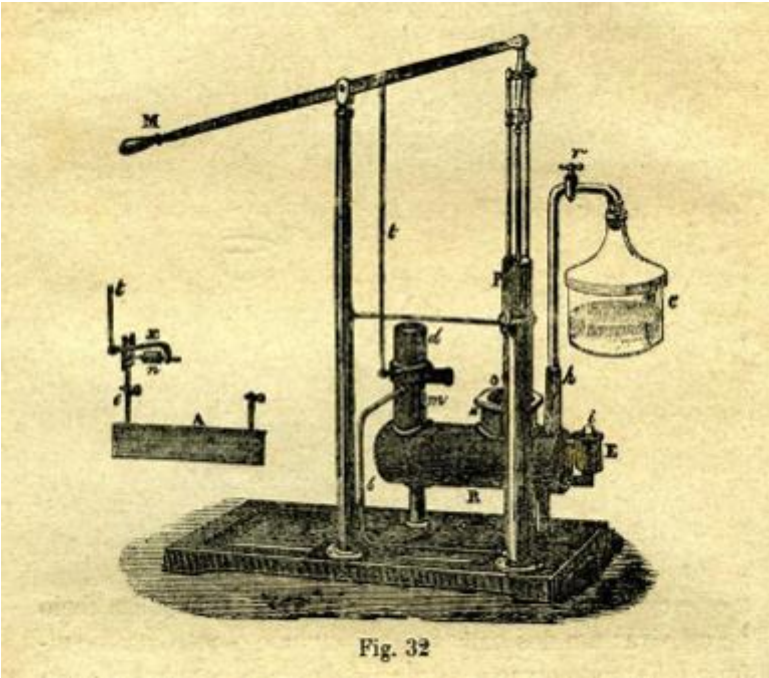


Fig. 3: Engraving representing an Edmond Carré's machine (Vidal; 1893).

Júlio Máximo de Oliveira Pimentel (1809-1884), the first Chemistry Professor of the Polytechnic School of Lisbon (between 1837 and 1864), mentioned on his chemical lesson's book chemical reactions where ice was used, for example, the hydrocyanic acid synthesis, the sulphurous acid synthesis and the hydrogen fluoride synthesis (figure 4). Adriano Augusto de Pina Vidal was a Physics Professor of the Polytechnic School of Lisbon (Vidal; 1893). He referred on the physical lesson's book the Ferdinand Carré and the Edmond Carré machines and there he described the mechanism of these machines.

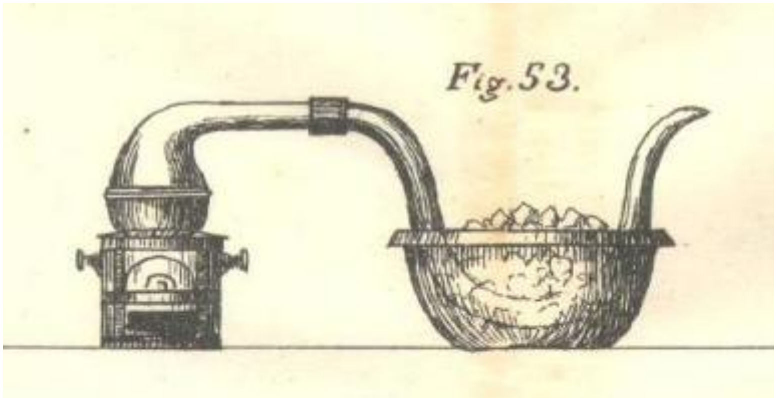

Fig. 4: Engraving representing the hydrogen fluoride synthesis (Pimentel; 1850).

Refrigeration apparatus in MCUL

As a case study we present the apparatus that belonged to the Polytechnic School of Lisbon. At the time there were a *Laboratorio Chimico* and a lecture theatre that is now part of the Museum of Science of the University of Lisbon's heritage. In parallel with these spaces, MCUL hosts a Historical Archive and a Cultural Heritage where Carré's apparatus are included.

The Museum of Science of the University of Lisbon's Historical Archive encloses documents concerning the icemaker apparatus acquisition, such as:[1]

- An account of expenditure for the *5ª Cadeira* of the Polytechnic School of Lisbon (1863) where we can read *'Ice maker apparatus' acquisition'*;
- An Invoice for the *6ª Cadeira* of the Polytechnic School of Lisbon (1869) which refers a *'Carré's apparatus acquisition'*;
- An account of expenditure for the *6ª Cadeira* of the Polytechnic School of Lisbon (1883) where we can see *'Remediation of a piece of ice apparatus'*

The Museum of Science of the University of Lisbon has three refrigeration domestic devices in its collection:

1. A refrigeration appliance which belonged to the Portuguese royalty –consists on a pneumatic machine for Leslie Experiments (MCUL153) (figure 5).
2. Ferdinand Carré's apparatus (MCUL 2035), actually displayed on the *Laboratorio Chimico*, the 19th historical space that belonged to the Polytechnic School of Lisbon (1837-1911) (figure 6).
3. An Edmond Carré's apparatus (MCUL 4294) (figure 7).

(Photo: M. C. Elvas, Courtesy Museum of Science, University of Lisbon)

Fig. 7: Edmond Carré's apparatus, MCUL 4294
(Photo: M. Peres, Courtesy Museum of Science, University of Lisbon)

Laboratorio Chimico and the lecture theatre of the Polytechnic School that are now part of the Museum of Science of the University of Lisbon's heritage suffered a restoration work between 1998 and 2007. The *Laboratorio Chimico* and its collection provide an excellent opportunity to look into the conditions of scientific practice of chemistry at the *Laboratorio Chimico* by the end of the 19th century. The restoration project of the *Laboratorio Chimico* included the restoration of a part of the Museum's chemistry collection. Ferdinand apparatus was one of those and it is displayed in the *Laboratorio Chimico* (figures 8 and 9).

Figs. 8 and 9: Ferdinand Carré's apparatus, before and after restoration, MCUL 2035
(Photos: M. C. Elvas, Courtesy Museum of Science, University of Lisbon)

The Ferdinand Carré's apparatus and its restoration was one of the several selected objects and results of a study which corroborates equipment with archival sources by establishing links between the collection and photographs, correspondence, reports, curricula, chemistry compendia, among other archival and bibliographical sources. These know-how then supplied the points of departure for further investigation and attempts for answering the following questions:

1. Which of the objects, present in the Museum collection today, were actually part of the *Laboratorio Chimico*? And for how long have they been used?
2. What was the context of their use during that particular period of teaching, research and development at the *Laboratorio Chimico*?
3. Which objects have supposedly been used, but are not to be found anymore in the collection?
4. When, from where and why exactly have they been purchased?

Ferdinand Carré's apparatus belongs to the objects set that could not be located on photographs, but could be identified in other documental sources of the archive, and still is present in the collection. This apparatus appeared on textbooks written by the professors, where certain experimental settings are described and depicted.

Carré´s apparatus: spread out

It was about the middle of the 19th century that the Carré brothers produced commercial machines for the freezing of water. Both machines operated by removing heat by vaporization of a volatile fluid. Edmond Carré's apparatus used the evaporation of water vapour at very low pressures and Ferdinand Carré's used the evaporation of liquid anhydrous ammonia.

The Carré's apparatus appeared in several catalogues of laboratory material of chemistry and physics; schoolbooks; medical, industrial and advertising publications; universal exhibitions and so on. Some examples are a 19th French advert (figure 10) in the *Revue des Instruments de Chirurgie* (1892).

Other Portuguese collections exhibit the Carré's apparatus, for example, the Science Museum of the University of Coimbra owns a Ferdinand Carré's apparatus (figure 11) and an Edmond Carré's apparatus.

From what was told above, the importance of this mechanical refrigeration can be seen, but with its development further applications have been made and used into many industries (Greene, 1916):

- In refining oils, refrigeration is used for the removal of certain paraffin products;
- In metallurgical operations, refrigeration allowed to get air of uniform quality;
- In textiles manufacture, in tobacco curing and cigar making, in perfumery making, in photographic films manufacture and other products.

REGULATIONS OF THE MINERAL CHEMISTRY LABORATORY OF THE POLYTECHNIC SCHOOL OF LISBON IN 1889

Maria Luisa Cordeiro Rolo LABORINHO DOS SANTOS ALVES
Universidade de Lisboa, PORTUGAL
luisa.laborinho@gmail.com

Abstract

Built "with the thought of filling the lack, in Lisbon, of (...) an establishment where at least the rudiments of natural sciences could be taught", the Polytechnic School of Lisbon appears as a space where science teaching reveals specific characteristics, and laboratory practice, in spite of several difficulties, is progressively introduced as an important factor in the teaching and learning process.
The works carried out in the laboratory of 6th course –General Chemistry and Notions of its main Applications to Arts– that transformed the old laboratory in the magnificent Mineral Chemistry Laboratory, constituted a landmark in the evolution of the experimental teaching in our country.
The Director of the Laboratory, Professor José Júlio Bettencout Rodrigues wrote very detailed regulations for the work in this laboratory that we will analyze in this communication. In his "Projecto sumário de Regulamento dos Trabalhos e Serviços do Laboratório de Chimica Mineral da Escola Polytechnica de Lisboa" *in 1889/1890 he specifies the rules related to the management of the laboratory, like the opening hours timetable in different days of the year, as well as some elementary safety rules. He also details the process of assessment of students. These regulations for the practical work in the laboratory are very complete, as compared to those of other laboratories at that time. They reflect not only concerns for the good management of the laboratory, but also pedagogical concerns related to the teaching and learning of good practice of the students, and are an important conquest in science education in Portugal. The laboratorial practice is gradually an important agent in the process of teaching learning that deserves to be remembered.*

Built "with the thought of filling the lack, in Lisbon, of (...) an establishment where at least the rudiments of natural sciences could be taught"[1], the Polytechnic School of Lisbon appears as a space where science teaching reveals specific

[1] FACULDADE DE CIÊNCIAS DE LISBOA (1937). *Escola Politécnica de Lisboa. Primeiro Centenário da Escola Politécnica (1837-1937).* Lisboa. 14 vols, 2, vol.1, pp. 5-6.

characteristics, and laboratory practice, in spite of several difficulties, is progressively introduced as an important factor in the teaching and learning process.

Founded in 1837, the pathway from its beginnings until the publication of the Regulations[2] in 1889, when the practical work in the 6th Chair (Chemistry) was implemented in a systematic, although not compulsory way, was not straightforward. That is, during about half a century, there was a large gap between the will for the implementation of practical work and its effective concretization.

Portugal, like other European countries, recognized the potential of chemical knowledge for the development of the country, and strove for the implementation of a quality teaching of this discipline. Vincent and Stengers refer a "global process of professionalization of sciences that occurred during the first half of the 19th century, affecting all fields of knowledge" and "where chemistry is frequently in the frontline" because "this process is due to an *effective* and not only formal transformation of the chemical practices"[3]. They also refer that "In the formation of chemical, experimental work is recognized as a necessity. It is no longer making some spectacular demonstrations before an audience of curious, but to train students in laboratory work".

In this context of *effective* transformation, the implementation of chemistry practical work in the laboratory of the 6th Chair –"the most expensive chemistry discipline and the one with most students"[4]– is significant and deserves to be pointed out, referring the professor who undertook this transformation, José Júlio Bettencourt Rodrigues. In 1885, after several unfruitful attempts to establish practical classes, he wrote a striking document addressed to the Polytechnic School Council, where he brings to light the "critical state of chemistry teaching"[5]. Finally he succeeded in changing the situation, making clear the need for major works that were, by then, carried out in the laboratory of 6th course – *General Chemistry and Notions of its main Applications to Arts* – transforming the old laboratory in the magnificent *Mineral Chemistry Laboratory*, which constituted a landmark in the evolution of experimental teaching in our country.

The letter that A. W. Von Hoffmann wrote to José Júlio Rodrigues[6], which is transcribed below (with our underlining), in its original language, reveals the importance of the laboratory:

> « Lisbonne, août 17, 1890
> Monsieur et très cher collègue.
> Je ne puis pas quitter Lisbonne sans vous témoigner ma reconnaissance pour l'accueil aimable que je dois à vous et à M. Lourenço.
> Il m'est à la fois un plaisir et un devoir de vous dire l'impression qui a produit sur moi la visite à l'École Polytechnique de Portugal. J'ai été étonné de trouver **un établissement de premier ordre, dont tout pays aurait droit d'être fier.**
> J'admire surtout les laboratoires et l'amphithéâtre de chimie. Ayant construit les laboratoires des universités de Bohn et de Berlin, **je crois posséder quelques connaissances des institutions chimiques, et je n'hésite pas d'affirmer que je ne connais pas un laboratoire mieux installé pour l'enseignement et pour la recherche.**
> Les salles de travail et l'auditoire commandant une profusion d'espace, d'air et de lumière que je n'ai pas rencontré souvent ailleurs. Permettez en outre d'ajouter **que je ne me rappelle pas un laboratoire où on a réussi à combiner d'une manière semblable l'élégance et l'utilité.**
> Adieu, mon très cher collègue
> Monsieur le Professeur José Júlio Rodrigues
> Votre dévoué
> A. W. Von Hoffmann »

The first practical course was opened in the academic 1889-1890 and it was a remarkable achievement with an epistemological, didactical and pedagogical range. This step in chemistry teaching required new regulations for the laboratory practice.

[5] RODRIGUES, José Júlio (1885). *op. cit.* , pp. 4-8.

[6] HOFMANN, A. W. von (1891). "Carta a José Júlio Bettencourt Rodrigues" in *Estabelecimentos Scientíficos em Portugal.* O Occidente, Lisboa, vol.14 (434), 11 de Janeiro, pp 13-14.

The Director of the Laboratory, Professor José Júlio Bettencout Rodrigues wrote very detailed regulations for work in this laboratory. In his "*Projecto sumário de Regulamento dos Trabalhos e Serviços do Laboratório de Chimica Mineral da Escola Polytechnica de Lisboa*" in 1889-1890 he specifies the rules related to the management of the laboratory, like the opening hours in different days of the year, the timetable for students and workers, as well as some elementary safety rules. He also details the process of assessment of students.

These regulations for the practical work in the laboratory are very complete compared to those of other Portuguese laboratories at that time. They reflect not only concerns for the good management of the facility, but also pedagogical concerns related to the teaching and learning of good chemistry practice of students, being a landmark in science education in Portugal.

Comparing the *Regulamento* with the two previous Portuguese laboratory regulations before 1889, namely:

1. *Regulations of the Chemistry Laboratory of the Commercial and Industrial Institute of Lisbon,* written by professor António Augusto de Aguiar, dating from 1872, with 20 articles (it includes organization, laboratory work, the kind of teaching applied, the way it was performed, and to whom it was directed. It doesn't refer to security rules. It doesn't offer general information about the laboratory work. It mentions who subsidizes the laboratory and the necessary funding);
2. *Regulations of the Practical Chemistry Course of the Coimbra University,* written by Professor Corrêa Barata, dating from 1879, with 12 articles (it includes laboratory work, functions of the auxiliar personel who work in the laboratory, and also conditions for admission to the course. It refers five safety rules: the student is required to remain in the designated place for the implementation of his practical work, having no access to any other lab space without permission. The student should show, in his practice, order and cleanliness. The use of small quantities of chemicals and "fume cupboards" is recommended. The poor performance or the breach of the rules is punishable by expulsion of the course).

Indeed, the *Regulations of the Mineral Chemistry Laboratory of the Polytechnic School of Lisbon* in 1889, reflect a change from a *"teaching that previously was nothing but mere individual attempts, without a pedagogic range"*, into a *"regular course with a special application, independent teaching, budget, reliable personnel and adequate material"*[7]. This document, besides presenting a significant difference, the details of the articles submitted, informs a lot about the practical chemistry at the time.

It has 66 articles, divided into three parts:

- The *first part* consists of *19 articles* specifying the general instructions for the functioning of the laboratory of the 6th course (chemistry mineral).
- The *second part*, details the "demonstration work at the 6th course and scientific investigations that could be performed in the laboratory". It consists of *two sections*:
  - First section - Experiments of the "general course", with 1 article;
  - Second section – Scientific work not related to the regular course, with 3 articles.
- The *third part* contains instructions for the students' laboratory work in the 6th course, with a total of *43 articles* in one section.

The students, who until then only visualized experimentation during the theoretical course, started to perform laboratorial practice during the practical course. However, at the beginning, the practical course was not compulsory. The practical teaching, although having no obligatory character at first, was aimed at repeating "the experiments seen in the course"[8], that are exposed in "special tables", similar to the experimental manuals used nowadays.

The first course started in the middle of November, 1889, and finished in May, 1890, "the students had to be present in at least 20 lessons of 2 hours each, with schedule to choose between 10 and 12 o'clock or between 10 and 14 o'clock"[9].

---

[8] OSÓRIO, Balthasar (1894). "José Júlio Bettencout Rodrigues – Licção de Abertura do curso de Chimica Mineral na Escola Polytechnica de Lisboa (1893-1894)". *Revista de Educação e Ensino*, Lisboa (9), pp.1-13.

[9] RODRIGUES, José Júlio (1889). *Projecto summario de regulamento dos trabalhos e serviços do Laboratório de Chimica Mineral da Escola Polytechnica de Lisboa posto em execução como experiência e sob a responsabilidade do respectivo Director no anno lectivo de 1889 e 1890*. Lisboa, Imprensa nacional.

The maximum number of students in a class was 32 (24 in the gallery and 8 in the ground floor. The students usually stood up and worked "dressed with a special gown and bare-headed."[10]

The rules stating the management of the laboratory includes the working days in the week and along the year, the opening hours in different days of the year; the access to the laboratory; personnel in charge and their duties; service areas of the laboratory; experiments of the general course. It also details the process of assessment of students, and the regulations also define the characteristics of the general course (registration, duration and functioning of the course, recommendations on the handling of chemicals and safety rules, equipment distributed to the students for their practical work, responsibility for the equipment, assessment and classification of the students).

Students assessment depended on their "tranquillity and moderation", "cleanliness", "accuracy and quickness", "special attention" on their "way of taking notes" and how they "answered the questions made by the chief in charge or the assistant lecturer during the works and on their notebook". *The notebook* should have the following characteristics: "in quarter" format, hardcover with at least 100 pages, firmly bound. The student´s name, registration number in the general course and in the laboratorial works should be on the cover, as well as his practical work schedule, and should stay in the laboratory. The quality notebooks and products obtained in these practical works were kept and archived as a merit evidence. The regulation is detailed in the rules that students must meet during the course of practical work.

The students were requested to extinguish any gas fire "no longer needed" and to spend only the water indispensable to their experimental work, only to use the strictly necessary quantities of the reagents for the experiments.

The student did not have access to the deposits of material, chemicals, or utensils they needed, without "written or verbal request".

Some of the safety rules were related with the evaporation or manipulation of concentrated acids, corrosive or volatile liquids, chemicals with an unhealthy or unpleasant smell, namely sulphidric acid –outside the fume hoods, it was forbidden; spilling of water or chemicals on the tables or on the floor, throwing paper or other debris on the floor; pouring corrosive liquids in the bench sink; throwing thick liquids, debris, filters etc. In any other than the specific sink is forbidden; and on the tables there should be special containers for collecting residues.

The student had a list of the equipment and chemicals that he received and he had to account for at the end of each academic year. There was an audit of equipment and utensils. The first student in each group of students was the supervisor of equipment and utensils. He had the duty to inspect equipment and tools assigned to the group.

In 1901 the practical course became compulsory and its classification accounted for up to 6 points (in 20) of the final classification. The Mineral Chemistry Laboratory was restored, and opened its doors as a part of the Science Museum of the University of Lisbon in 2007.

"LABORATORY HANDS" ONCE MORE AND THE POLYTECHNIC SCHOOL OF LISBON (1837-1911)[1]

Sandra LOPES, Isabel CRUZ
CICTSUL – Centro Interdisciplinar de Ciência, Tecnologia e Sociedade, Universidade de Lisboa, PORTUGAL
sandra.lopes.3@netvisao.pt
isabelnevescruz@netcabo.pt

Abstract

In two previous papers presented at the 6th International Conference on History of Chemistry, held in 2007 at Leuven, and 7th International Conference on History of Chemistry, held in 2009 at Sopron (Hungary) we brought up some facts regarding the identification of the chemistry preparers personality in some teaching institutions in Portugal, namely in the Polytechnic School of Lisbon. In those papers we also endeavoured to distinguish aspects of the professional evolution of the mentioned individuals.

In spite of being basically employed to assist the lecturer and relieve him of the so called minor preparatory tasks, necessary for the practical classes and investigation, the laboratory hand would, when needed, alternate between a mere laboratory assistant helper to practically an assistant lecturer. Yet, it is clear that there was a barrier that prevented the lecturer and the hand –each with a totally independent professional situation– from being mistaken one for the other.

New significant data provided by the intensive research done in documentation from the Polytechnic School archive, as well as in other exterior sources, related to the current CICTSUL project, "Scientists, laboratories and scientific instrumentation in the Polytechnic School of Lisbon" (later to become Faculty of Sciences), lead us to the necessity of delving deep into this issue. Therefore, the present work proposal approaches again the question of that specific professional area –the laboratory hand– and its role in the development of Chemistry teaching in Portugal, using the Polytechnic School of Lisbon as a case study. The objective is to outline more accurately the general points of evolution within the perspective of their work with the Chemistry lecturer, professor or investigator, and thus provide a better understanding of the historic process of Chemistry and its development in the educational institutions of the 19th century.

[1] PTDC/HCT/81550/2006 Project "Scientists, Laboratories and Physics and Chemistry Scientific Instrumentation of the Lisbon Polytechnic School" financed by FCT.

Introduction

Despite the reputation of the scientific education institutions to which they were connected, Chemistry Preparers – also known as Laboratory Hands– were almost always absent from the records of its history. However, recent research about the development of chemistry teaching in Portugal has taught us more about them and how they were, or were not, a part of Chemistry tuition. This is what is intended to be addressed in this project, in the specific scenario of the Polytechnic School of Lisbon (1837-1911).

The Polytechnic School was established in January 11th, 1837 to provide scientific expertise in the training of Army and Navy soldiers and had, ever since its establishment, a subject of Chemistry named "6th Subject: General Chemistry and its main applications to the Arts". Later in 1859, another one was created: "Chemical Analysis and Organic Chemistry".

Between the moment of the creation of the School and the creation of the new Chemistry subject, a dramatic event radically changed the physical space allocated for this training project. On April 22nd, 1843, a devastating fire completely destroyed the interior of the old building of the Polytechnic School –the same building where the College of Nobles, abolished on January 4th 1837, once was. The rebuilding of the School would finally take place in 1846. Ten years later, there was a new Chemistry Laboratory at the Polytechnic School.

Before 1843, practical classes for the 6th Subject were performed in a chemistry lab: lacking a purpose built location, the kitchen of the boarding school which preceded the Polytechnic may have been –after some interventions– the interim solution in effect until 1843.

After the great fire, the Chemistry and the Physics class were transferred to the Royal Mint's Chemistry Laboratory. Some equipment that survived the fire was moved from the Polytechnic School to the Royal Mint, and located in the small houses by the Metallurgical Laboratory. In 1851, the Chemistry class was still held at the same Laboratory, headed by Júlio Máximo de Oliveira Pimentel, and with José Alexandre Rodrigues as lab preparer instead of Francisco Cardoso Leal Júnior, who had left around 1847.

With José Alexandre Rodrigues' resignation as lab preparer in 1854, it is certain that the activity of the first two chemistry lab preparers was undertaken in labs, either preceding or exterior to the historical building. It is, in a way, a pre-historical era to the Chemistry Laboratory of the Polytechnic School and its laboratory hands.

1837 to 1859: The Chemistry Laboratory within the one subject system

The development of chemistry and other issues related, such as the history of Chemistry preparers at the Polytechnic, has a primordial factor of analysis in its key subjects: the 6th Subject and Chemical Analysis and Organic Chemistry.

Until 1859, Chemistry at the Polytechnic was taught as one subject subdivided into two topics which themselves evolved with time. Initially and according to organic law, the first topic (or 1st part) constituted the elementary course and the second was reserved for the more developed areas of Chemistry. Students at the Polytechnic attended both parts of the 6th Subject or just the second one, according to the degrees they were reading. In the first section, lasting for 4 months, subjects such as cohesion, affinity, nomenclature, atomic theory and isomerism were taught; metals and metalloids and finally, organic chemistry. However, this system of separating Chemistry into an elementary course and a development course was not maintained over time, as can be seen in the programme for 1856/1857, where the 1st part is Inorganic Chemistry and the 2nd is Organic Chemistry.

But since 1840/1841 there was a programme for a practical course under the 6th Subject lecturer's remit: "practical lessons on manipulations". It is legitimate to ponder that this course was initially based on the Chemical Analysis element, present in his 6th Subject programme of 1838: "instruments and reactants –their use; analysis of gas, solid matter, alloys, acid mixtures and rock, organic and mineral water analysis".

It is still unknown how these practical lessons on manipulation worked in the chemistry lab. Later, according to the chemistry lab programme in the academic year of 1856/1857, the practical lab lessons –a given number of preparations and analysis– occurred between October and February as part of the 2nd part of the 6th Subject –Organic Chemistry.

The chemistry lab functioned under the direction of the 6th Subject lecturer. Given that as from July 1853 there was a new lecturer position specifically for Chemistry, since that date through to 1860 there were four people with direct intervention in the chemistry lab: the Director (and 6th Subject lecturer), his substitute, a preparer and an attendant.

The Chemistry Lab and the two subjects of Chemistry (1859 to 1889)

The need to coordinate education at the Polytechnic School with that of the war schools –namely that of the army– was not only a constant priority but also necessary given its position as introductory institution to the army and navy. Even if the creation of the subjects of Chemical Analysis and Organic Chemistry on the 7th of June 1859 can be regarded as a return of a civilian environment to the School, the fact is that the military impression lasted for a long time. Only in 1869 did the School Head become a civilian post undertaken by a permanent or retired lecturer, whilst previously it had been held by a General or Senior Officer of any of the Scientific Weapons.

According to the Lisbon Polytechnic School's programme, established on the 8th June 1860, the distribution of subjects across the various introductory courses, Army, Navy and for the main degree, Chemistry is only available in the latter. It is in the legal system of 1860 –which was followed for many years with only slight adjustments regarding the Army and Navy Schools– that Organic Chemistry becomes a full part of the "Chemical Analysis and Organic Chemistry" subject where it remains for over 30 years, mainly aimed at surgeons.

However, in 1896 another reorganisation of the Army School led to further changes in the Polytechnic's programme, when Organic Chemistry was established as a requirement for all candidates to Engineering, Weaponry and Civil Engineering, thus gaining a new found importance within the curriculum.

The first lecturer of this subject was Júlio Máximo de Oliveira Pimentel. The curriculum he organized for the subject of Chemical Analysis and Organic Chemistry for the academic year of 1860/1861, consisted of a first part (October to January) of quantitative and qualitative chemical analysis, and a second part (January to July) of organic chemistry. This is another fact that points to the theory that chemical manipulation topics from the 6th Subject through to the single subject system, was in fact a chemical analysis course, operating for a long period with the organic chemistry topics, perhaps because inorganic chemistry was always very extensive and didn't allow for it. Come the moment of the separation of Chemistry into two branches (organic and inorganic), the analysis topics remained attached to organic chemistry to the extent that the subject was called "Chemical Analysis and Organic Chemistry".

In April 1864, Agostinho Vicente Lourenço became the senior lecturer for this subject after Oliveira Pimentel's retirement. The programme for Organic Chemistry –apart from the generic topics– now presents a special segment dedicated to the development of its specific content. Chemical Analysis also benefits from an expansion here, with the inclusion of urine and blood analysis, toxicological experiments and spectroscopy.

During the 1860's the following group is perceived at the School: the director (a chemistry lecturer), his preparer, two lab preparers (for the 6th Subject and Organic Chemistry), and two attendants (one for Mineral Chemistry and one for Organic Chemistry).

According to Agostinho Vicente Lourenço's own statement, at the end of the 1870's the actual physical organization of the space already depicted a division between organic/inorganic subjects. However, this seems to be true only for the lecturer's work, not the students. In the early 80's the chemistry lab had two separate areas for organic and inorganic chemistry, and each respective lecturer was also director for their particular section. This situation –one lab with two sections– was maintained through the next decade despite some attempts at establishing new labs for chemical analysis and organic chemistry.

1889 to 1890: The Chemistry lab in practical context of the 6th Subject

The presentation of the educational programme of Chemistry classes at the Polytechnic would not be complete without addressing a significant moment of its existence: the creation of a practical subject for the 6th Subject, by José Julio Bettencourt Rodrigues back in 1885. At this point he presented to the School Board various proposals striving to improve the teaching of Mineral Chemistry.

In Bettencourt's understanding, the chemistry lab needed a complete overhaul. It also needed an increase in staff. He suggested a substitute Chemistry lecturer due to there being over 100 students attending the 6th Subject, and the resulting need for multiple forms. He also defended the need for a technician, besides the lecturer. This new technician was named "Assistant Chemist to the 6th Subject" –at times also referred to as the Head of Practical Work– and had as a primary objective the facilitation of the practical course (experimental chemistry) which José Julio Rodrigues wanted to establish at the School.

In the lecturer's proposal, the preparer chemist should be "an experienced practitioner, read in the best chemical practical processes, with vast lab experience and versed in chemical analysis and knowledgeable in Chemistry as a whole". It was through Roberto Duarte Silva's recommendation (at the time the professor of Analytical Chemistry at the Central School of Arts and Manufacturing in Paris) that Bettencourt Rodrigues found the right person: Charles Lepierre, recent graduate in chemical engineering from the Municipal School for Industrial Physics and Chemistry in Paris, where Roberto Duarte Silva also taught.

According to information sought from Charles Lepierre himself, the practical 6th Subject began in 1888-1889 in a lab which meanwhile was subject to major reformation. In the next academic year, 1889-1890, according to the Mineral Chemistry Lab programme which came into circulation, the practical subject was an elective subject, but with influence on the final grade, which basically worked in accordance with terms proposed back in 1885. Given Charles Lepierre's departure, the second year of the course was not achieved with the same collaborator.

During the period in which the 6th Subject practical course was active, the Chemistry lab at the Polytechnic belonged to its students, who occupied all the available space, including the galleries. It is thought that this may have been the cause for the lack of lab space for the Chemical Analysis practical course, hence motivating the search for a new lab location in the *campus*. It seems that (and delving slightly into the next topic) there was no practical course for the 6th Subject in the third year. José Julio Rodrigues was absent from the Polytechnic School, and Eduardo Burnay, recently transferred as substitute chemistry lecturer, assumed the role based on his wide experience as interim lecturer.

The last decade of the 19th century

As the last decade of the 19th century began, there was only one chemistry lab and only one director. The year 1883 opens a new chapter in the institution's history with the passing of the two Heads of both Chemistry subjects, and the consequent entrance of new lecturers in 1896: two army officials, Aquiles Machado for the 6th Subject and Tomas Cabreira for the Chemical Analysis and Organic Chemistry. Under the guidance of Aquiles Machado, the practical element gains new demands and contributes alongside assiduity to a heavier portion of the final grade. Meanwhile, a December 1893 decree appoints a new chemistry lab preparer who is believed to assume a supporting role in the tuition of the subject of Chemical Analysis and Organic Chemistry. En route to the 20th century, with no increased headcount in the Faculty and with an insignificant increase in lab staff, the School accumulates hardships in furthering practical teaching.

The search for solutions to this problem sets lab preparers –it is believed that for the first time– in a position to openly assume Faculty functions: "explaining subjects and topics exposed in the theoretical classes" within the remits of the practical class. This evolution is especially significant given the historical divide between lecturers and lab preparers: the latter were not allowed to teach, nor regarded as tutors, until then.

Chemistry Lab Preparers in the Polytechnic School (1837-1862)

The chemistry lab preparers were chemistry lab employees. In their job description, teaching was not to be found, hence they should not be regarded as candidates to, or successors of a professor.

The first lab preparers –those active between 1837 and 1861, and between Francisco Mendes Cardoso Leal Júnior, and Manuel Vicente de Jesus– may be incorporated into First Class Pharmacists, a hierarchy assumed between peers (there were two classes, although they were not contemplated by law), to distinguish between those who graduated from a Pharmacy degree and those who were eligible through work experience to sit the admission exam. Although legally both classes were eligible for admission, only First Class Pharmacists were allowed to access certain functions such as First Operator of the Lusitanian Pharmaceutical Society (certified to perform official analysis), and that of lab preparers in Higher Education.

They were, consequently, savvy chemical analysts especially with regards to water quality, chemical, fiscal and judicial matters, such as product adulteration and poisoning suspicion, as well as those with terms of Chemical relevance. These were the ones who accompanied the teaching of the 6th Subject of Chemistry at the Polytechnic, the paradigm of unique subject tuition.

But this continuity must have been disturbed with the new subject of Chemical Analysis and Organic Chemistry, since the discomfort of the Pharmacists regarding this new branch (Organic Chemistry) was evident, given that it was not a part of their own education. This was still the case in 1868, as Pharmacists claimed attendance to Chemical Analysis and Organic Chemistry from the Polytechnic or the University of Coimbra to be mandatory for admission of 2nd class candidates, and as a foundation course for eligibility for the Pharmacy degree, alongside the 6th Subject, which was already required.

Organic Chemistry and the Lab Preparers of the Polytechnic School

The moment of creation of a new Chemistry subject –"Chemical Analysis and Organic Chemistry"– and the appointment of a new senior lecturer in 1859 was critical for the institution. Agostinho Vicente Lourenço was a Chemist from Goa that had travelled to France, England, Germany and made contact with several renowned chemists abroad. Some years after the creation of this new subject, many foreign collaborators started working in the Chemistry lab. These were known as the "German lab preparers" although their nationality wasn't yet totally confirmed. It is believed that because pharmaceutical students stopped reading Chemical Analysis and Organic Chemistry, this might have influenced the recruitment in this sector and induced demand abroad due to the lack of domestic response.

From 1862/63 and for more than ten years, the presence of these collaborators is perceivable. They came to collaborate with Organic Chemistry and normally stayed in that position for a short period of time. Emílio Dias, an industrial chemist, was the only Portuguese lab preparer in this group.

Well into the second half of the 19th century however, and given the development of technical fields where Chemistry was an important subject, such as agronomy or industrial chemistry, new areas of growth were constantly revealing themselves across the nation, resulting in the increased probability of admission of a chemistry lab preparer at the Polytechnic. This was the case of César Justino de Lima Alves, named lab preparer in 1893, provisional chemistry demonstrator in 1898 and finally instituted as permanent demonstrator in 1900. As an agronomy graduate appointed according to article 99 of the 28th July 1886 decree, he was able to leave the country for two years to attend practical courses of Chemical Analysis in French and German labs at the expense of the Portuguese state. It was after his internship between 1890 and 1892 at the Agricultural Chemistry lab from the Agronomy Institute of Paris, within the Department of Agriculture and under the chemist Achilles Müntz as well as the Orth in Berlin, that Lima Alves arrived at the position of lab preparer at the Polytechnic. His exposure to chemistry practices applied to the context of agriculture must have given this agronomist special characteristics for the Chemical Analysis and Organic Chemistry course. César Justino da Lima Alves was nominated interim professor at the Superior Institute of Agronomy in 1911, becoming its Director between 1915 and 1916.

Having progressed from a lab preparer to a demonstrator, and then further to assistant lecturer, alongside with the progress and perspective the new Century had brought, this personality will bridge the gap through to the 20th century and undertake some of the most relevant developments in the role and expectations around lab preparers.

The transition into the 20th century: becoming the School of Science

Until the creation of the University of Lisbon (March 1911) and the consequent evolution into the School of Science, the subjects made available at the institution allowed for degrees of Chemistry, Inorganic Chemistry, Organic Chemistry and Chemical Analysis. This way a match was made between the institution's offer, and the demand for diversified education and related scientific grants (army and navy officials, surgeons, pharmacists, agronomists and vets) sought through the Polytechnic School over the years.

However, in 1911, with the University reform, important introductions and updates were made to the reigning programme of varied subjects of chemistry, namely the Biological and Physio-Chemistry programs which were so widely accepted. Lab preparers still remained even after the creation of the School of Science and those who qualified under the Polytechnic School were granted access to the Faculty as first assistants (César Justino da Lima Alves, nominated in 1893 as lab preparer) or second assistants (João Rocha, nominated in 1900 as lab preparer and assistant analyst of the Chemistry lab). António Dionísio Garras, Eurico Humberto Tavares Moreira, Daniel da Conceição Torres or Álvaro Pacheco de Teves, amongst others, are the new generation of "post Polytechnic School lab preparers" awaiting to be discovered and labelled.

Abstract

From the time of its discovery, photography participated in the production of evidence in many scientific fields. In the second half of the nineteenth century the quality of the photographic images as well as the discovery of easier and more reliable photographic techniques, transformed photography in a precious tool for scientists; they were now able to register in an indirect way atmospheric and magnetic phenomena.
Throughout Europe, Meteorological and Astronomical Observatories had started to be equipped with photographic self-recording instruments in order to be able to register in a continuous way temperature, pressure or atmospheric electricity variations. One of these Institutions was the Kew Observatory, considered one of the best in Europe.
By the end of the nineteenth century, the Infante D. Luiz Observatory of Lisbon, the Meteorological and Magnetic Observatory of the University of Coimbra, as well as the Meteorological and Magnetic Station of Oporto, owned photographic self-recording instruments for meteorological and magnetic purposes: barographs, psychrographs, electrographs and some magnetographs.
Portuguese scientists established privileged scientific contacts, namely with the Director of the Kew Observatory, Balfour Stewart (1828-1887) and with William Thomson (Lord Kelvin) (1824-1907), among others. In this paper we will present our research on the instruments, photographic processes and photographic data, as well as on the contributions of Portuguese scientists in this field focusing on the international cooperation between Portugal and other European countries.

Introduction

In 1839, the French physicist François Arago (1786-1853), presented to the Academy of Sciences in Paris the works of Louis Daguerre (1787-1851) and Joseph Niépce (1765-1833) relative to Photography. He considered with great forecast the contribution that photography would have for science and art. In his speech, Arago indicated the perspectives of use of this discovery as indispensable to the scientist in the areas of Astronomy, Archeology and Spectroscopy, among others[1].

Scientists quickly became aware of the capacity and importance of the photographic technique in the production of evidence in many scientific fields. In the second half of the nineteenth century the discovery of easier and more reliable photographic techniques, transformed photography in a precious tool for scientists; they were now able to register directly the image of nature captured with a photographic camera (figure 1), or in an indirect way, through the reading of data for a natural phenomenon in a photographic self-recording instrument.

Meteorological Observatories throughout Europe

The Royal Observatory of Greenwich in London (figure 2) played a major role in the history of astronomy and navigation, and it is best known as the location of the prime meridian. The observatory was commissioned in 1675 by King Charles II. At this time the King also created the position of Royal Astronomer. John Flamsteed (1646-1719) was the first to be appointed as director of the observatory. The earliest known measurement of magnetic declination was made by Flamsteed in 1680.

The difficult nature of magnetic and meteorological observations led to the development of automatic recording devices. Between 1846 and 1852, the English surgeon Charles Brooke (1804-1879) invented a series of self-recording instruments which used photography for the automatic registration of meteorological and magnetic data. A coal gas light-source, mirrors and optics to amplify readings and a clockwork drum covered in photographic paper to record the results were used (BROOKE; 1847; 1850; 1852). These instruments included a barometer, a thermometer, a psychrometer, and a magnetometer (figure 3)[3]. An example of a photographic record using these instruments is shown in figure 4. These type of self-recording instruments were adopted at the Royal Observatories of Kew and Greenwich, Paris, and other meteorological stations around the world.

The Kew Observatory was an astronomical and terrestrial magnetic observatory founded by King George III in Richmond, Surrey. In 1842, the Council of the Royal Society proposed to establish, in connection with the British Association, a Physics Observatory in order to improve the knowledge of meteorology and magnetism. A Committee was created to construct a self-recording meteorological apparatus to be employed at the Kew Observatory (SCOTT; 1885).

A purchase order for a set of meteorological and magnetic instruments to be used for the self-registration of atmospheric data was granted to the meteorologist Francis Ronalds (1788-1873). In 1847 Ronalds presented to the Royal Society a description of the photographic self-recording instruments (RONALDS; 1847). These instruments (electrometer, thermometer, barometer, and declination magnetometer), were very similar to the instruments in use at the Royal Observatory of Greenwich.

In 1859 Balfour Stewart (1828-1887), a Scottish physicist, was appointed director of the Kew Observatory. He became interested in doing research on meteorology and terrestrial magnetism. These instruments were designed by J. Wesh and constructed by the maker Patrick Adie from London (STEWART; 1859). In the following year Stewart published "An Account of the Self-recording Magnetographs at present in operation at the Kew observatory" and presented a plate with its description (figure 5).

The first report (1867) of the Meteorological Committee of the Royal Society imparted a considerable impetus to the manufacture and use of these instruments (HICKS; 1886).

In 1885 several Observatories were supplied with Kew Pattern Magnetographs: Batavia, Coimbra, Lisbon, United States, St. Petersburg, Florence, Stonyhurst, Utrecht, Melbourne, Bombay, Mauritius, Vienna, Zi-Ka-Wei, San Fernando, Potsdam, Brussels, and Nice (SCOTT; 1885). The Kew Observatory was in the second half of the 19th century an important center of the internationalization of physics, and more specifically, of geomagnetism (MALAQUIAS; 2005).

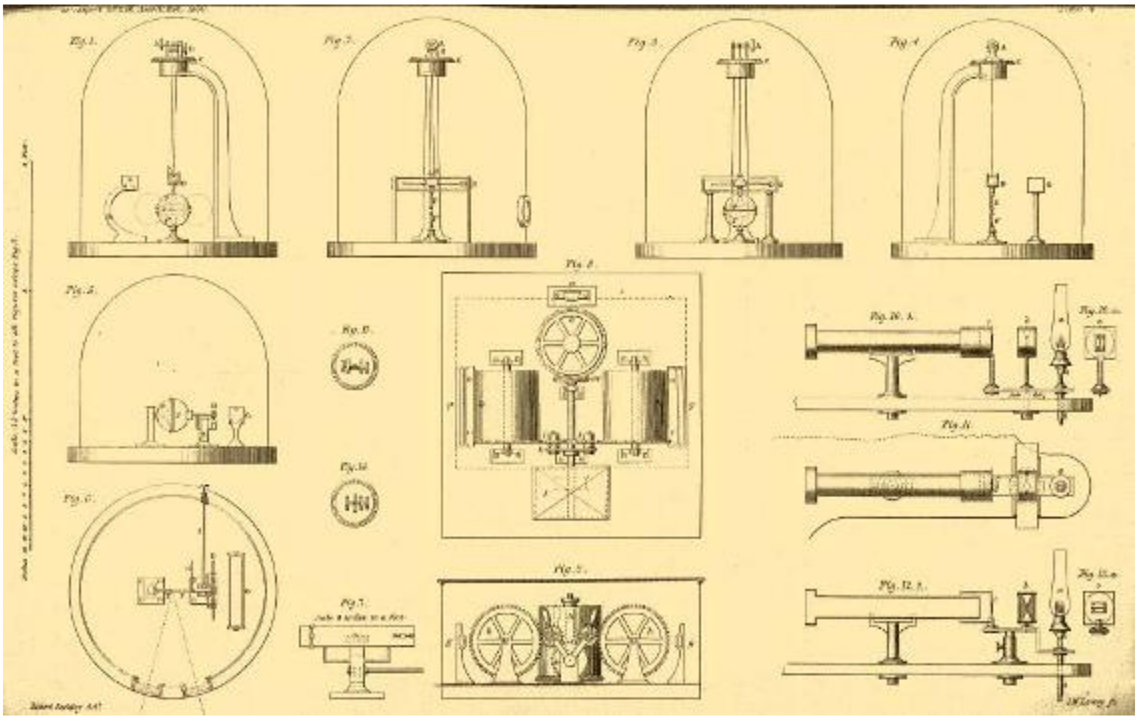

Fig. 5: Self-recording magnetographs (STEWART; 1860).[4]

Portuguese Meteorological Observatories

In the 1850s, the Lisbon Polytechnic School and the University of Coimbra submitted to the Portuguese government proposals to implement their own geomagnetic observatories and to collaborate with the already existing international network. Portugal joined the Magnetic Union in the summer of 1857.

Brito Capello (1841-1917), observer from the Observatory of Infante D. Luiz (figure 6), made a scientific trip to the Paris and London Observatories, to become acquainted with the instruments used in these institutions. Following Brito Capello's advice the Lisbon Observatory bought some instruments: magnetographs and the Thomson's electrograph from the maker Patrick Adie of London, and the baropsychrograph from the maker Jules Salleron of Paris (OBSERVATORIO Infante D. Luiz; 1862).

In 1860, with the same purpose, Jacinto António de Sousa (1818 -1880), a physicist professor from the University of Coimbra, visited Madrid, Paris, Brussels, London, Greenwich, and Kew. In a report presented to the respective University authorities he referred the reasons to adopt the Kew model for the magnetographs, a Thomson's electrograph and a baro-psychrograph from Patrick Adie. The Coimbra Observatory (figure 7) acquired these instruments in 1866 (SOUZA; 1862; 1875).

By the beginning of the 20th century (1903), the Directors of the Observatories of Lisbon, Coimbra, Oporto and Azores (respectively A. Pina Vidal, A. Santos Viega, F. Paula Azeredo and F. Afonso Chaves) decided to organize and distribute among their institutions the tasks of meteorological and magnetic determinations. Coimbra was responsible for the magnetic data and the Observatory of Oporto (figure 8) for the study of atmospheric electricity. Following this decision, a Kelvin-Mascart quadrant electrometer was bought in 1904 for this Observatory (MACHADO; 1949).

Photographic self-recording instruments

William Thomson (Lord Kelvin) published for the first time a description of a divided-ring electrometer in the Memoirs of the Roman Academy of Sciences in 1857 (THOMSON; 1857). Later on, in 1865 the Portuguese periodical *Annaes do Observatório do Infante D. Luiz* reported a description of the Thomson's electrograph working method with the photographic register of atmospheric electricity variations in a continuously mode. The system for these measurements was composed by three units: one container full of water working as a collector (figure 9b) that was connected by a copper wire (A) to the electrometer (figure 9a); in its inside is suspended by a platinum wire an aluminum needle (a). This needle electrified by the Leyden bottle (b) becomes very sensitive and detects the variations of atmospheric electricity transmitted to the metallic semi circle (c); the air inside was dried with pieces of pumice stone imbibed with sulfuric acid in the lower part (h) of the electrometer unit . Above the needle is suspended a small round mirror (e) that reflects a beam of light to an adequate rotating cylinder unit, covered with a photographic paper able to register the needle deviations.

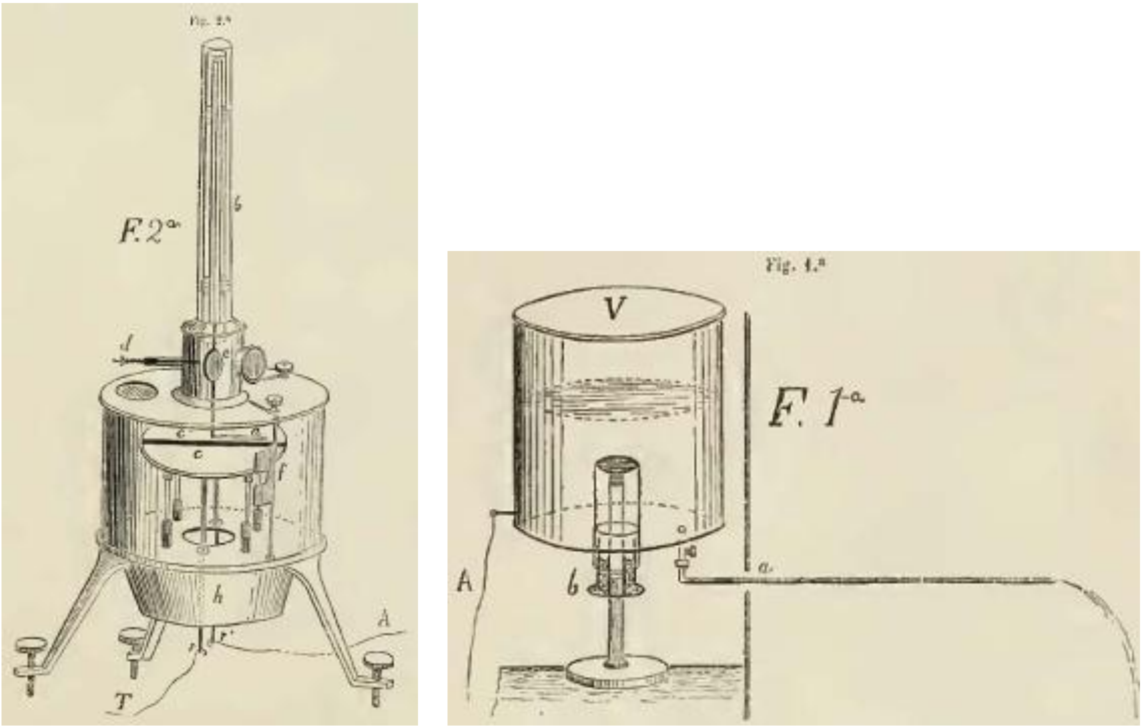

Fig. 9 a, b: Thomson's electrograph (SILVEIRA; 1865).

Brito Capello observed that sulphuric acid wasn't strong enough to dry the air and he wrote to William Thomson asking for advice on this problem. In his letter (figure 10), Lord Kelvin explains to Capello how he used the electrometer in order to get results with more accuracy for the studies of atmospheric electricity and the technique of photographic data recording (THOMSON; 1864).

Later, in 1867, Thomson presented, in a Report to the British Association of Science, an improvement to the previous design, including a light mirror which would indicate deflections of the moving body and substitution of the half rings by four quadrants[5] (figure 11).

Another instrument, Branly's electrometer, an improvement on the Thomson's electrometer was in use by 1877 in the Lisbon Observatory (OBSERVATORIO Infante D. Luiz; 1877)

[5] This instrument used the electrical force generated between charged electrodes. A butterfly-shaped electrode with two quadrants of a circular disk is supported by a torsion fiber inside a stationary circular box composed of four quadrants, with opposite pairs of which are electrically connected. The rotation of the suspended electrode depends on the potentials applied to the various electrodes.

Fig. 10: William Thomson's letter to Brito Capello: 22/12/1864 (IGIDL).

Fig. 11: Thomson's quadrant electrometer (c.a. 1867), MCUL00331 (M. Peres 2008).

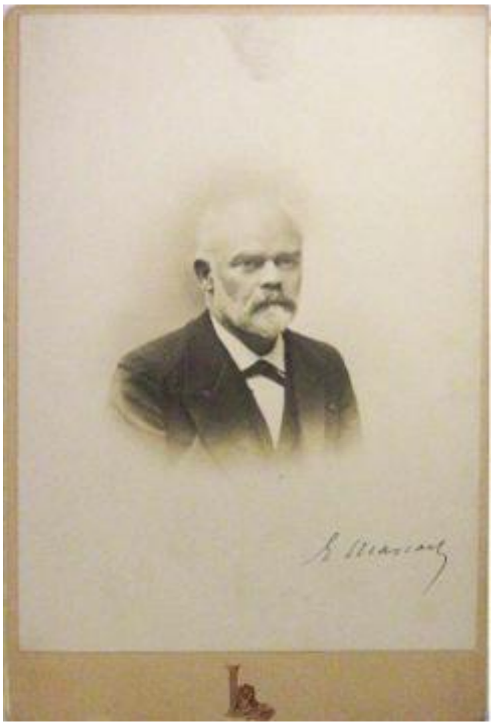

Fig. 12: Éleuthère Mascart's photo (Photographie des Grands Magasins du Louvre à Paris, c.a.1890) (IGIDL- Photographs folder).

Later on 1883 a further improvement of the Thomson's electrometer was described by the French physicist Éleuthère Élie Nicolas Mascart (1837 – 1908), in *La Nature* (MASCART; 1883). This new instrument was constructed by the French maker Carpentier.

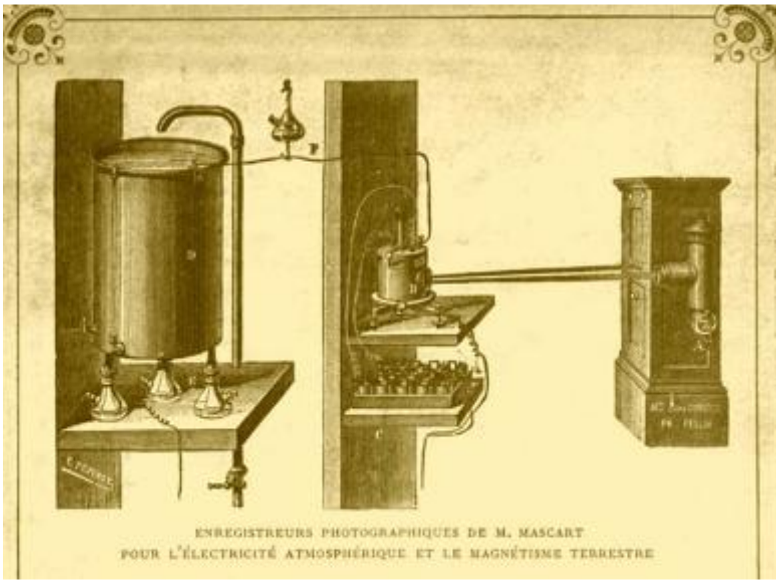

Fig. 13: Self-recording instruments for the electric potential,
adapted from Mascart (Ph. Péllin Catalogue; n.d.).

In figure 13 Mascart's self-recording electrometer is shown, comprising the collector (water drop system, isolated by Mascart's insulators), the electrometer with a Daniell's battery with ten elements, and on the far-right, the lantern with a gas lamp and the box with the photographic paper.

The Oporto Observatory in 1904 bought a Mascart's electrometer from the maker Carpentier with a Daniell's battery with a fifty elements. The photographic register and the lantern were bought from the maker Pellin (figure 14). However, the first experiments in atmospheric electricity started only in 1927.

Fig. 14: The photographic system from the Kelvin-Mascart Electrometer
(Instituto Geofísico da Universidade do Porto – photograph, courtesy of Marisa Monteiro, MCUP).

In 1864 Fradesso da Silveira, Director of the Infante D. Luiz Observatory, reported a new instrument: the baro-psychrograph (figure 15). This was a self-recording instrument that would simultaneously register pressure and temperature (readings of dry-bulb and wet-bulb thermometers) in two photographic papers, with the same lamp (SILVEIRA, 1864).

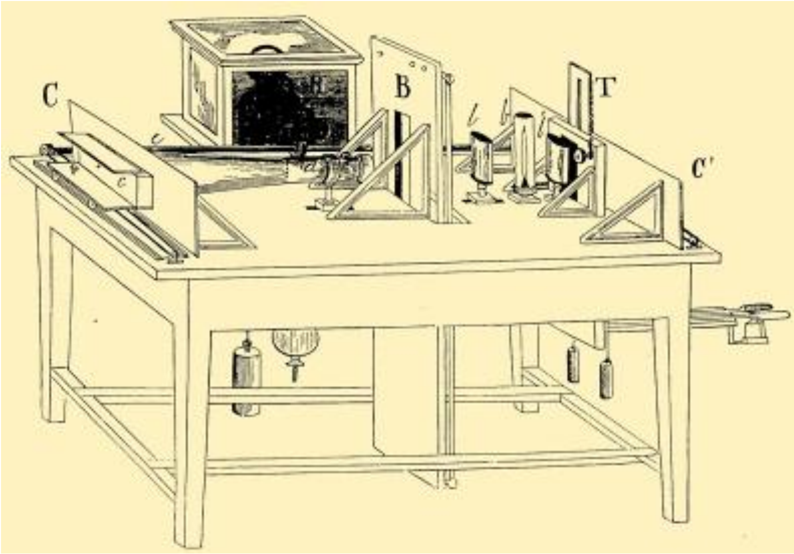

Fig. 15: Salleron's baro-psychrograph (SILVEIRA, 1864).

In Coimbra a baro-psychrograph made by Patrick Adie was also acquired in 1867. According to Jacinto de Souza, the Observatory's director, it was a unique instrument because it has resulted from scientific discussions between the maker and himself[6] (CORTE REAL; 1872).

In the Observatory Infante D. Luiz under the direction of Fradesso da Silveira the magnetographs (made by Adie) were in regular operation by the beginning of July, 1863 (figure 16).

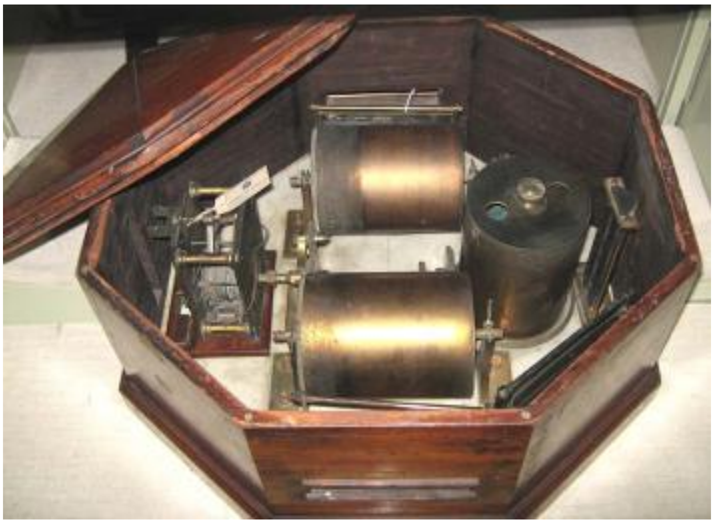

Fig. 16: Octagonal box with devices for registering the magnetographs (MCUL.00354) (Photograph by Marília Peres).

These magnetographs worked until 1902. According to Fradesso da Silveira: *"The three magnetographs were placed in the vault room on the first floor"* (figure 17) (SILVEIRA; 1864).

[6] The whereabouts of this instrument are unfortunately not known.

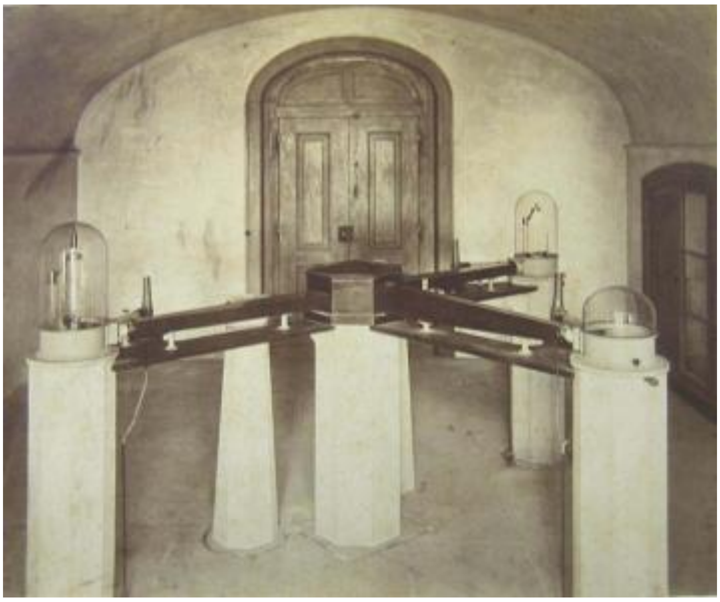

Fig. 17: The magnetographs' room (Archive of Ajuda Astronomical Observatory, Folder 723).[7]

In the context of the referred international collaboration, Brito Capello sent some copies of the Lisbon magnetic curves to Stewart, superintendent of the Kew observatory. The corresponding data (figure 18) of two observatories was discussed in a paper by Capello and Stewart published by the Royal Society (CAPELLO & STEWART; 1864).

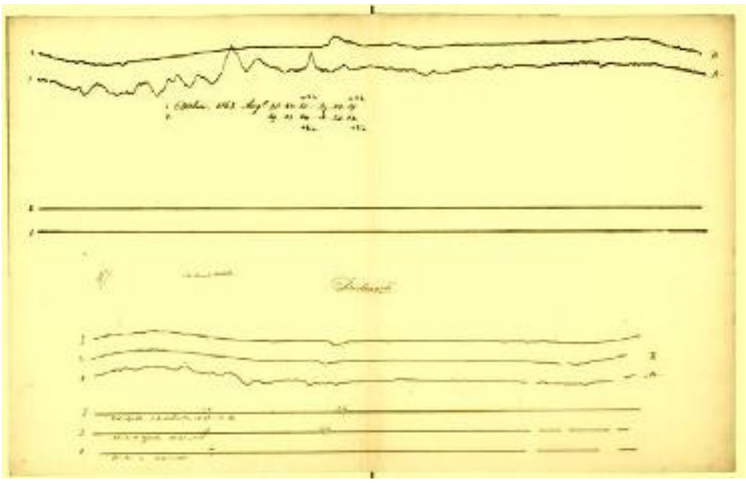

Fig. 18: Photo-lithographic Impressions of traces produced simultaneously by the magnetographs at Kew and Lisbon (Kew and Lisbon Observatories, 1864).

The first attempt to register magnetic data in the Meteorological Observatory of Coimbra was in 1867. However, some problems were reported by Jacinto de Souza: humidity, inconstancy of the gas-lamp light and the operators inexperience (Souza; 1875).

These magnetographs worked until 1930, when they were replaced by the Askania Model. The 19th-century instruments (figure 19) are now in the collection of the *Instituto Geofísico da Universidade de Coimbra*.

[7] This photograph was found in the archive of the Ajuda Observatory, in Lisbon. An identical one taken by Francisco Rocchini, entitled. "Astronomical Observatory at Ajuda", belongs to the collection of Arquivo Fotográfico da Câmara Municipal de Lisboa no. 8179" (PAVÃO; 1990).We think it represents the vault room referred by F. Silveira.

Fig. 19: The declination magnetograph; IGUC (photograph, Marília Peres).

The Geophysics Institute of the University of Coimbra holds an important collection of magnetograms from the long period of studies on geomagnetism at the Coimbra Observatory, since 1867 until today. These magnetograms are an important source for the study of solar activity. In figure 20 is shown a relevant example of one of this magnetograms; the great solar storm that took place on the 24th-25th October, 1870, is registered in this magnetogram. This photographic recording was studied in 2008 by Vaquero et al (VAQUERO; 2008).

Fig. 20: Photographic recording, IGUC (Photograph: Marília Peres).

The photographic process

The first known description for the photographic process, for self-recording instruments, was made in 1847 by Charles Brooke in the Philosophical Transactions (BROKE; 1847).

> *“ (…) to prepare by a ready process photographic paper sufficiently sensitive to receive the feeble impressions of artificial light, and at the same time sufficiently durable to retain those impressions during a period of at least twelve hours, as a more frequent attention to the apparatus would probably interfere with the ordinary arrangements of an observatory”.*

The paper was sensitized with silver bromide and a small quantity of silver iodide, and he used isinglass[8] as a catalyst in the development of the photographic image. The paper used in the photographic process was previously washed with a solution of silver nitrate. A saturated solution of Gallic acid with a very small quantity of acetic acid was used as a developing solution. The paper was then washed two or three times in water and the image was fixed with a solution of sodium thiosulphate.

For the chemist and physicist William Crookes (1832-1919) the advantage of the photographic process in self-recording instruments was in the sharpness and definition of the image which made it convenient for later consultation. However, there was a problem: the shrinkage of the paper when the chemical substances were applied. Crookes made an improvement. He used the wax-paper process invented by Gustave Le Gray (1820-1884) to prevent paper shrinkage and distortion of the image during its development in baths and washing of the chemical substances. He applied successfully the process to the barograph and the thermograph of the Radcliffe Observatory (CROOKES; 1857).

The crucial difference between the calotype and the wax paper process was in the preparation of the paper. In the calotype process the first step was the sensitization of a sheet of high quality paper with a combination of silver halides. After exposure in a camera the image was developed and fixed with sodium thiosulphate. The translucency of the paper negative could be increased by saturating with wax. This helped to increase the contrast and shorten printing times. In most respects, the preparation of wax paper negative parallels the preparation of the calotype, except for one important difference: in Le Gray's wax paper negative process, the paper was saturated with wax before the chemical sensitization. This simple reversal of one step deeply altered the quality of the photographic paper, improving its wet strength.

Finally, the most practical advantage offered by the new negative process was its impressive longevity. Because of the protective qualities of wax, a week's supply of fully prepared paper could be stored (CROOKES; 1857). This process was used by Balfour Stewart in Kew in 1859 and in the Coimbra Observatory.

To enhance stability, a gold toning bath using gold and sodium chloride was added to the positive proof, which also gave an artistic finishing to the photographic image (STEWART; 1860).

Final Notes

- The use of photographic devices for meteorological and magnetic studies has been crucial for its development.
- The photographic process had the advantage of improving the sharpness and sensitivity of the data record.
- The wax-process prevented paper shrinkage and distortion of the image during its development in baths and washing of chemical substances.
- A remarkable improvement of scientific instrumentation and data processing systems, in a short relatively period of time, was achieved by these institutions.
- European Observatories exchanged a great deal of information through an intensive use of scientific correspondence and circulation of publications, books and periodicals.

Abstract

This paper attempts to provide a general overview about the way in which foreign scientists influenced Brazilian medical and anthropological discourses about race and miscegenation during the second half of the 19th century and the beginning of the 20th century, it is, coinciding with the introduction of evolutionism in Brazil.

The perils of miscegenation: the influence of foreign science on Brazilian racial thought

Throughout the nineteenth century, whenever Brazilian doctors or naturalists approached the study of “human races” and, therefore, the apparent problem of racial mixture, they did so looking for scientific models previously produced in Europe or the United States. The influence of those foreign analyses on Brazilian scientific discourse on races was imponderable. Emperor D. Pedro II would look continuously for European or American experts in order to lead and organize many of the first scientific institutions in the country: «A French team composed by Emmanuel Liais, Louis Cruls and Henrique Morizo was chosen to direct the *Imperial Observatory*, (...);Claude Henri Gorceix, a French as well, created the *School of Mines of Ouro Preto*, Hermann von Ihering, German, worked as a prominent naturalist in the *National Museum* and was the organizer of the *Museu Paulista*; Emil Goeldi, Swiss, founded the museum that has his name in Pará, Charles F. Hartt and Orville Derby, (...) Americans, took part in the formation of the *Geological Commission of the Empire* (later named *Mineralogical and Geological Survey*) and the *Geological Commission of São Paulo*, Franz W. Dafert, Austrian, started agricultural research in Brazil, with the *Agronomic Institute of Campinas*... »[1].

[1] SCWARTZMAN, S. (1990), Os estrangeiros na ciência brasileira, *Ciência Hoje*, vol. 11, 62, p. 12

The foreign presence in the Brazilian scientific milieu was so significant that it would even take a complete control over some of the best national scientific institutions. For example, out of the total number of scientific articles published by the *Revista del Museu Paulista* –the Journal of the São Paolo Museum, led by the German Hermann von Ihering– , only a tiny part was produced by Brazilian researchers. The rest was signed exclusively by European naturalists, a good number of whom where travellers, often hired temporarily to collect and analyze different samples of scientific interest. In a similar way, considering the *National Museum of Rio de Janeiro* –where, in 1877, Dr. Lacerda would inaugurate the first Anthropology course in the country–, out of the 44 members of the editorial board of its official journal, the *Archivos do Museu Nacional*, there were just three Brazilians[2].

This clear dominance of foreigners in the Brazilian scientific institutions was noticeable at all scientific levels. However, the influence of foreign scientific doctrines and theories was particularly sensitive when the discussion pointed to the natural status of the different human races present in the Brazilian society. In other words:

> «It is impossible to deny the enormous influence of European racial theories among the Brazilian intellectuals of late nineteenth century. The national intelligentsia expressed a systematic concern with the multi-ethnic origin of the Brazilian people, which was perceived as a source of social contradictions and as a potential barrier to the construction of an authentic national identity. 19th century Brazilian society –with deep historical roots based on slavery and a system of class domination overlapped with the racial hierarchies– constituted a perfect target for such theoretical influences»[3].

Brazilian Doctors, anthropologists, and natural scientists would readapt those scientific proposals coming from abroad, often giving them an original Brazilian character, as in the example of Raimundo Nina Rodrigues. As Nina Rodrigues pointed out in his pioneer work on the linkages between miscegenation, degeneration and crime in Brazil[4], some of the best naturalists and anthropologists of the most "progressive" and "civilized" nations of Europe and North-America had already studied the problem of racial fusion of the colonies before any Brazilian had tried to attempt that task (in fact, Nina himself was the first Brazilian to do so extensively). Moreover, as Nina explained, many of those foreign scientists had written about Brazil, as a giant natural laboratory for the experimental study of the social and biological effects of miscegenation. Therefore, it was worthy to learn carefully from those studies.

Neutral or favourable descriptions of Brazilian miscegenation were very rare among the international scientific community during the second half of the 19th century. In any case, even if they were taken into account –as in the case of Quatrefages, whose ideas on racial mixture were quoted by Nina Rodrigues–, the influence of these indecisive, if not contradictory, defenders of racial mixture was certainly incomparable with the influence of the defenders of the opposite point of view, for whom Brazilian miscegenation was estimated as a source of decadence and degeneration. Among this last group, a prominent place must be assigned to Count Arthur de Gobineau, who had lived in Rio de Janeiro as the French ambassador between 1869 and 1870, and eventually became a personal friend of Emperor Pedro II. Gobineau's influence in Brazilian scientific circles would be remarkable for decades, and even authors whose work was developed many years later, such as Nina Rodrigues himself, would keep using some of the ideas defended by the French Count as one respectable source for research on racial degeneration, recalling the Count's dramatic description of the «decline observed in the South-american mestiços»[5].

During his stay in Rio, the famous author of the Essay on the Inequality of the Human Races (1853-1855)[6], reported how, with moral and aesthetic horror, he had been a privileged witness of the racial peculiarities of Brazil: «no Brazilian has pure blood; all possible combinations of marriages between whites, blacks and Indians have proliferated to such an extent that the nuances in the colour of the skin are endless, and this has resulted –both in the lower as in the upper classes– in the saddest of degenerations»[7].

According to the French diplomat, the deleterious effects of Brazilian miscegenation were so patent that, following his calculations, decay caused by interracial crosses would «inevitably condemn the degenerate mestiços to disappearance (...)

in about two hundred and seventy years»[8]. It was a very similar opinion to that maintained by another illustrious French visitor of Brasil, the eminent botanist and naturalist Auguste Saint-Hilaire, who, some years before Gobineau –during the course of his travels along the Brazilian coast and the diamond territories of the inner-lands– could observe «a horrible population, formed from the mixture of oppressed and oppressors»[9]. In his view, Brazilian Indigenous peoples constituted only «the sad remnants of a civilization that will quickly fade away, accompanied by the disappearance of the unhappy race to which it belongs»[10]. Tristes Tropiques …

No more flattering that the previous prognostications, the future of Brazilian people resulted equally dark for one of the greatest naturalists of the century, Louis Agassiz –who visited the country between 1865 and 1866. In his travel notes, he described the devastating effect that, on his mind, racial mixture had caused to the nation: «Those who doubt about the pernicious effects of racial mixing and, led by a false philanthropy, try to deny all the natural barriers existing between the human races, should come to Brazil. Here, better than anywhere else, it is not possible to deny the racial decline resulting from the crosses. They could not deny that miscegenation shuts down the best qualities of each races: in whites as in blacks or Indians, racial mixture produces an indescribable kind of hybrid, of poor physical and mental energy»[11].

Agassiz, as it is well known, used anti-evolutionary and creationist arguments to explain the natural differences between the human races –considered by him as different zoological species–, as well as the harmful effects of interracial crossing between them. But in Brazil, a country where –unlike in other Latin American states– the theories of biological evolution were accepted in the main national scientific institutions without much tension[12], these kinds of old fashioned anthropological arguments would rapidly be forgotten and replaced by more modern evolutionary arguments about the natural origin of the racial divergences. In the following section, we'll consider the impact left in the Brazilian scientific milieu by another group of scientists who, in the last part of the century, had already assumed the modern evolutionary theories, and were applying them to the study of the natural differences between human races.

Evolutionism, polygenism and the racial debate in Brazil

In the last decades of the 19th century, racial theories inspired in the Darwinian vision of human evolution –a biological struggle for survival between human groups, according to a scale of evolutionary perfection culminating in the "favoured races" and, especially, in the white man[13]– received an enthusiastic reception in Brazil. This was especially the case of different polygenist anthropological models of human evolution that defended –as previously had been done by Morton, Agassiz, and others in non evolutionary terms– that the major racial groups had evolved as completely different species, from a remote common ancestor. As it has been stated by Thomas Glick, a good part of the Brazilian elites –among which the Emperor himself, Don Pedro II, should be included in a prominent place[14]–, would receive this evolutionary racial theories with open arms, even before the advent of the Republic and the abolition of slavery. Paradoxical as it may seem – given the close connections that, traditionally, linked those Brazilian ruling classes with Catholicism–, many «members of the Catholic elite were prompt to accept polygenic evolutionary models of human evolution as a scientific justification for the maintenance of white supremacy in the social realm. Therefore, in spite of being Catholic, those elites could be reinforced by accepting the polygenic models of human evolution»[15].

Moreover, during the last decades of the 19th century, a good portion of the Brazilian scientific institutions that tried to make diagnostics and/or give potential solutions to the "problem" of miscegenation –such as Natural History Museums, Ethnographic Museums, Colleges...– were created and oriented under clear polygenist principles. As it is well known, polygenist models of human evolution –mostly developed in Europe and America during the late nineteenth and early twentieth centuries– defended that the human races were actually different species, evolved from a common ancestor. The

[14] The emperor Pedro II was a notorious admirer and financial promoter of different scientific projects, both in Brazil as in other countries. A member of the Paris Academy of Sciences (which only counted with 8 foreign Academics), he even got to give economic support to some of Louis Pasteur researches.

[15] BERTOL, H., ROMERO, M. and GLICK, T. (2003), *A Recepção do Darwinismo no Brasil*, Rio de Janeiro, Ed. FIOCRUZ, p. 23.

product of their mixture –the mulatto, or the *mestiço*–, although fertile, was defined for the poligenists as a real "hybrid". Some of the best physical anthropologist of the time, such as the French Paul Broca, defended that, notwithstanding their inter-fertility, those racial hybrids were often defective or inferior to the parental "pure" lines from a biological point of view[16]. In this sense, racial miscegenation could only constitute a process leading to both social and biological degeneration.

Assuming these same principles, some of the most prestigious Brazilian doctors and anthropologists of end of the century, often described the anatomy or physiology of these "hybrids" as "atavic". In this way, many scientists and academicians believed that the Brazilian population –which was essentially *mestiça*– was characterized by a whole range of abnormal features and stigmata, originated through undesirable racial crossings. A good part of the white learned elites considered that this supposed racial degeneration that affected the country had been caused by miscegenation. Nina Rodrigues, as many of his disciples, admitted that only the "upper grades of the miscegenation scale" –in which clearly dominated the Caucasian component–, could reach the same capacity for intellectual progress and "civilization" as pure whites. In all the other cases, the *Mestiço* constituted a kind of human sub-product, especially prone to biological and mental degradation. They could not be treated as the same kind of citizens –both at a legal and at an intellectual level–; on the contrary, they should be considered and judged under different standards since, considering numerous parameters, those hybrids were closer to a child than to an pure Caucasian adult. In this sense, one of the first books written by Nina was devoted to defend, from a medical point of view, the need for separate penal codes for whites, blacks and *mestiços*[17].

Since the last decade of the nineteenth century, the "problem of miscegenation" would always be considered from an evolutionary point of view by the Brazilian natural scientists. In order to understand the Brazilian reception of Darwinism and its applications to the racial question, it should be remembered that Darwin himself had visited different parts of Brazil, and commented the effects of the Brazilian racial mixture as he had observed during his voyage aboard the Beagle. In some of his later works, –and despite his definite belief in the unity of the human species[18], and his own personal belief in the existence of «many excellent and kind-hearted mulattost»[19]– Darwin admitted that «when two races low in the scale are crossed, the progeny seems to be eminently bad. Thus the noble-hearted Humboldt, who felt none of that prejudice against the inferior races now so current in England, speaks in strong terms of the bad and savage disposition of *Zambos*, or half-castes between Indians and Negroes; and this conclusion has been arrived at by various observers. From these facts we may perhaps infer that the degraded state of so many half-castes is in part due to reversion to a primitive and savage condition, induced by the act of crossing, as well as to the unfavourable moral conditions under which they generally exist»[20]. Darwin also recognized that, during his stay in South America, « many years ago, long before I had thought of the present subject, I was struck with the fact that, in South America, men of complicated descent between Negroes, Indians, and Spaniards, seldom had, whatever the cause might be, a good expression»[21].

But, in addition to Darwin, this same theoretical framework, in which miscegenation was contemplated as a potential source of evolutionary degeneration, was taken as an absolute a priori by some of the most pioneering evolutionary schools of anthropological thought of the end of the 19th century. Such was the case of the French Anthropological Society, led by Paul Broca, whose theories about human hybridization between different human species were published in 1860 –it is, prior to Darwin's writings on the subject– with the suggestive polygenist title of «On the phenomenom of Hybridity in the *Genus* Homo»[22]. Perhaps because of a simple question of linguistic closeness, the newest advances and theories of foreign science came to Brazil mainly through French publications (even though, in Brazilian scientific libraries, such as in the Medical School's Library in Salvador de Bahia, there could also be found scientific books in Italian, in English and, to a lesser extent, in German). For that reason, the French anthropological school (which included some of the most notorious polygenist thinkers of the time, such as Paul Topinard, Clémence Roger, or Gustave Le Bon), had a decisive influence among Brazilian physicians interested in the study of the "human races", as in the so-called "problem of degeneration" caused by racial mixture.

Nina Rodrigues' "medical school" in Bahia, in particular, resulted decisively influenced by the French school of physical anthropology. Some of Nina's works were responsible for the dissemination in Brazil of French poligenist discourse

about racial mixing. For example, the main theses of Nina's *Métissage, dégénérescence et crime*, that is, considering «miscegenation as a degenerative influence in the social aetiology of crime»[23], had been previously exposed –as Nina himself recognized–, in French by Darwin's translator Clémence Roger. Nina also used Gustave Le Bon famous studies on "the psychological laws of the evolution of peoples" as an authoritative anthropological source of information. There, he read and learned about «South American *mestiço* populations as being the incontestable proof of the disastrous social effect of racial mixture»[24].

But French racial thought also influenced some other leading Brazilian evolutionists working outside Bahia. The Pará Museum of Natural History was led by the Swiss naturalist Emil Goeldi, who had learnt about poligenism from Haeckel himself, since the German scientist –who defended the existence of 12 different human species– had been his scientific mentor in Germany. In São Paulo, as well, polygenist evolutionary discourse was introduced by some of the leaders of major scientific centres, such as the *Museu Paulista*, directed by the German Hermann von Ihering. His views about the nature of Brazilian populations can be easily understood through his own words: «degeneration, as frequently observed in the hybrids of the animal kingdom, is easily seen among the crossed products of the different human groups»[25]. Von Ihering himself somehow seemed to legitimize, in biological terms, the extermination of a group of Indians Kaingang who, reluctant to abandon their own lands, had entered in war by the white settlers. Von Ihering –defending the need for the construction of a railway that, starting from Sao Paulo, passed through the Kaingang territory– had invoked evolutionary principles to defend the expulsion of the natives on the bases of their evolutionary inferiority in the struggle for life. According to him, what actually condemned the «inferior indigenous groups» to extinction was nothing else than «nature herself», against whom it would be childish to invoke any kind of «humanist moral principles»[26].

Similarly, the Polytechnic School in Rio de Janeiro was directed by the French evolutionism defender Louis Couty, who, notwithstanding being contrary to slavery, expressed a strong belief in the intellectual and biological superiority of the Caucasian. Couty thought that blacks were actually inferior to Europeans by their biological and intellectual nature. But at the same time he also defended that their natural inferiority didn't imply the superimposition of slavery, as an unjust social penalty over those races who had been previously been "punished by nature". Couty believed in an innate natural "black laziness" that was, «in part, responsible for the backwardness of the country: even when they [black people] recovered freedom with emancipation, they did nothing to work or cultivate land or for social progress». According to him, despite slavery constituted an abhorrent institution in moral terms, it had functioned as a practical protection at the social level for the blacks, since, during that period «they were well fed, cared and protected against old age or Unemployment»[27]. Perhaps the greatest of all evolutionary naturalists living in Brazil at the period, the German Fritz Müller, showed total confidence that German immigration soon will help to make the Aryan race become the dominant racial element in the south of the country. German blood will soon overpass «the Latin decadent element», which, according to him, contributed to much of the backwardness of Brazilian populations.

Meanwhile, the two main scientific directors of the National Museum of Rio de Janeiro during the last decades of the nineteenth century, Ladislau Netto –who led the museum until the nineties– and João Batista de Lacerda –his immediate successor–, will support an extremely racist and polygenist biological anthropology. Deep admirers of the French School of physical anthropology developed by Broca and Topinard, since the 1870's they started a series of anthropometric research on the physical characteristics of the indigenous breeds of Brazil, publishing their results in the museum Journal, the *Arquivos do Museu National*. Also inspired by the work of the North-American polygenist Samuel Morton –who, decades earlier, had used his cranial metric data to defend that "human races" were actually completely independent species[28]– they began to form a collection of Brazilian skulls in the museum.

Both for Lacerda as for Netto, it was unquestionable that Aboriginal Brazilians came from a different evolutionary lineage than Europeans. In order to show this evolutionary diversity, they organized a great anthropological exhibition which counted, as the main attraction, with living Brazilian Indians, exposed as living representatives of the most brutalized kind of men: the First Brazilian Anthropological Exhibition, held in 1882 at the Rio de Janeiro National Museum.

SCIENCE DE-INTERNATIONALIZED? THE CHALLENGES OF A LEARNED SOCIETY IN THE POST-NAPOLEONIC ERA

Magne NJÅSTAD
Department of History and Classical Studies, Norges Teknisk-naturvitenskapelige Universitet i Trondheim, NORWAY
magne.njaastad@ntnu.no

Abstract

Learned societies of the 17th and 18th centuries formed an international network for exchange of scientific ideas and results through correspondence and circulation of publications. The era of the French revolution and the Napoleonic wars meant a blow to this network. In the post-Napoleonic era, learned societies had to find their place in a new order of scientific knowledge, where the universities were to play a more important part.
This paper will deal with how one such society, The Royal Norwegian Society of Sciences and Letters, met these challenges in the period ca. 1810-1870. The society, which had been founded in 1760 in the city of Trondheim, had participated in the international exchange of scientific knowledge through the network of learned societies, but by the turn of the century, it found itself in a peripheral position, both due to the lack of active members, but also hastened on by the troubled political situation. The Society met this challenge by reinventing itself as a locally based organization, aiming to play an important role on the national stage, and with pretences to uphold its international network.
The first two goals were successfully achieved, but the society struggled to place itself in a meaningful international context. Most successfully, this was done in the exchange of publications and the maintenance of the best scientific library in Norway, and partly it was done by trying to engage the personal networks of the leading members abroad. By the second half of the century, it was obvious that these strategies had to be based in a scientific environment of a more professional nature, such as a university or a research-based museum. The latter course was chosen by the society around 1870.

The topic of this paper is "The de-internationalization of science", which is a too complicated way of saying "the breakdown of scientific communication" when it comes to the phenomenon of learned societies in the 19th century. So the matter to be discussed is why the learned societies played a less important role in the 19th century scientific communities, and what strategies they had to try to keep up an international network. I will mainly be using The Royal Norwegian Society of Sciences and Letters, situated in the city Trondheim as an example, but also with some glances at the other Scandinavian societies.

But first we need to sort out a little. What were the learned societies and their networks, and how does the society in Trondheim fit in with these?

The learned societies of Europe had their heyday in the 18th century. The movement was initiated with the establishment of The Royal Society in London in 1660, and the Royal Academy in Paris in 1666. Both can be seen on a background of renaissance academies, but at the same time represented something new –scientific endeavour and communication outside the frameworks of the medieval universities, in the spirit of enlightenment. In the run of the next century, societies and academies, sometimes private, but mostly under royal protection, established themselves all over Europe. They formed a network of learned persons, exchanging knowledge, publications and artefacts in the spirit of enlightenment.

The Society in Trondheim was a part of this movement or network, with some peculiarities of its own. The society was founded in 1760 by a troika consisting of the bishop Johan Ernst Gunnerus, the headmaster at the cathedral school Gerhard Schøning, and well-to-do amateur Peter Fredrik Suhm. In a matter of a few years, they had organized a society who counted among their members both local clergy and public officials, and international intellectual superstars such as Carl von Linné. What they all had in common was an enthusiasm for collecting and sharing knowledge.

The sharing of knowledge in an international network between societies and their individual members took several paths. One was corresponding individually, in the knowledge that information in a private letter was likely to be shared with the equal-minded. But other ways were publishing, and trading.

Publishing transactions was an important side to the activities of the learned societies, stemming back to the 17th century Royal Society in London. The society in Trondheim lost no time in embarking on the same mission. From 1761, a more or less yearly volume of the writings of the members of the Society appeared. The volumes were published in Danish, but for the first decade, a parallel edition in German was also published, thus making the results of the struggles of the Norwegian scientist available to a larger public. These results would be of a varying nature. One of the special traits of the Trondheim society is that it was more than usually preoccupied with theology, and interpreting nature in its light. Another peculiarity, not connected to this, was that access to membership was fairly unrestricted –there was not an upper limit to the number of members of the society. But to return to publishing: The founding members were the most active ones in publishing in the society's series. But other members contributed as well. Once the volumes were published, they would enter the network of trading. The library of the Society in Trondheim was to no little degree augmented by trading volumes of transactions and the like from similar societies around Europe.

Another trade in which the societies engaged, was in artefacts. A learned society with self esteem had a collection, perhaps an exhibit, of objects of great rarity, beauty or significance. The Society in Trondheim could contribute to this network of trading objects with peculiarities of the north –stuffed birds, pressed plants etc from the arctic region. Not the least through bishop Gunnerus' network of priest in his northern diocese, the society had an abundance of these objects.

But these golden days did not last. The period of general warfare over pretty much the whole European continent from the early 1790s were a blow to the network of learned societies. The French convent, for instance, abolished all national academies and literary societies. Warfare also had its say in the disintegration of the networks. The academy of Berlin was plundered by French troops in 1806, while the academies in Brussels, Turin and Bologna were closed more or less permanently from the early 1790s, sometimes to the end of the Napoleonic wars. In Trondheim, we find an example of the difficulties of communicating with other societies, when an outstanding member of the Turin academy opened a correspondence in 1811 on the topic of classifying species of fish, and a long discussion was held at this meeting on how to organize correspondence that could break through the British blockade of the North Sea.

James McClellan, in his work on the learned societies of the early modern period, points to three paths of re-emergence for the learned societies once the turmoil of the Napoleonic wars was over. One path, particularly found in France, was that the societies became independent research institutions with a paid staff. Another option, more often found in the German area, was that the societies became more closely tied to the emerging universities; Berlin is a prime example here. The third possibility was that the societies fell into decline and became regional elite associations, more based on social value than scientific activities. The Trondheim society landed on a combination of the first and last of these three options: A locally based society with little scientific activity of its own and where the social value of membership was regarded as high, but on the other hand wealthy enough to support scientific work done by others in a relatively impressive manner, at least once in a while.

But keeping up the international networks was a harder challenge, not only for the Trondheim society, but for others as well. The publications went on, but not as before. From the 1790s the transactions of the society were published at a more seldom rate; from the beginning of the 19th century at intervals of ten years or more. This was not to change until the second half of the century. And already from the 1770s, the transactions were published in Danish, later in Norwegian only. The value of the publications for a foreign public must have been diminished by this. Nevertheless, trading publications with other societies remained an important way of keeping up the network throughout the 19th century.

But one of the main problems, seen from the side of the societies, was the emergence of the universities as a more important scene for scientific research. The societies had been the forums of the educated amateur, who didn't necessarily have scientific investigations as his sole occupation, but more as a way of life. The development of the scientific world in the direction of specialization and professionalization was not easily compatible with the learned gentlemen or local clergy who dabbled in disciplines of their liking. And even though the more central and established of the societies developed in the direction as mentioned above –as professional institutions of research or affiliated with universities, the more peripheral societies, such as the one in Trondheim, had no chance of accomplishing this. An alternative strategy for them was to try to upkeep their networks by electing foreign members who might contribute to the society in one way or another. This was a strategy followed to some degree in Trondheim. In the first years of the union with Sweden, a number of Swedish members were elected into the society. But a number of these were connected to the king's court, and were elected at the time of King Karl Johan's coronation in Trondheim. These members contributed to a very little degree to the activities of the Society, other than the letting nimbus of the royal court shine upon it. More serious was the policy of the president of the society in the 1830s and 40s, Frederik Moltke Bugge. Bugge was granted by the government the means to travel through Europe to study the organisation of higher education. This he thoroughly did over several years, and the contacts he made during these travels were often elected as members of the society at his request. However, these members hardly contributed to the society's activities beyond their mandatory contribution of books to the society's library at their election.

Another way of trying to recruit foreign members was to elect any passing stranger that seemed to fit the requirements of membership. Needless to say, this wasn't a very successful strategy either.

One noteworthy exception must be mentioned. Among the passing strangers in Trondheim was also the Recherche expedition in 1838. This French-led expedition to the arctic region was an early example of a cross-discipline research-project with members from several nations. The expedition consisted on scientists of both natural sciences and social sciences, in addition to a group of artists to illustrate their work and findings. The expedition was French, but relied heavily on cooperation with both Berlin University and Alexander Humboldt, and the Royal Swedish Academy of Sciences. The Trondheim Society's role in the expedition was modest indeed, as it amounted to hosting a special meeting of the society for the members of the expedition when the research vessel "La Recerche" anchored in Trondheim for a few days in June 1838. And of course, members of the expedition were elected as members of the Society.

Some attempts were also made to elect members that could contribute to the growing natural collections of the society. The election of the botanical gardens and zoological museum of Calcutta in the late 1840s might point in this direction. This coincides with a restoration and upgrading of the natural collections of the society. But it seems that not much came of it.

Perhaps one further explanation of why the society invested so little in keeping up their international contacts lies in the nature of what the society –and to a degree also the other Scandinavian societies– were preoccupied with. In the case of the Trondheim society, attention was to a fairly large degree turned to subjects of a strictly Norwegian nature –and published in Norwegian. Norwegian history, language, geology, botany and marine zoology were fields where much money and research was invested. That wouldn't necessarily collide with an international outlook, but it seems that the framework for these activities now to a larger degree were in a "nation-building" framework.

We might see something of the same in Denmark –the Royal Danish Academy of Sciences and Letters had been involved to a large degree in the literal mapping of Denmark through triangulations in the late 18th century, and this interest in the Danish realm and culture was only to expand in the following century. The Danish Society, however, was able to keep up its international relations through a more active policy of electing foreign members throughout the 19th century. The number of members of the Danish society was limited, and by 1830, foreign members would comprise more than half of the members. Their share would then decline for some decades. The Danish society on the other hand cut itself off from sharing their scientific activity with foreign societies and scientific institutions by publishing their transactions in the vernacular, as did the Norwegian society. Under the reign of the secretary Hans Christan Ørsted (who was secretary from 1815 to 1851), the policy of promoting the Danish language was an important issue for the society. Partially, this was done by investing a lot of time and money in publishing a dictionary of the Danish language.

On the other hand, the society was involved in an impressive expedition circumnavigating the globe in the years 1845-47, making many valuable observations during the journey. The expedition had both political and scientific goals. The political goal, to maintain Danish presence and rule over the Nicobar Islands in the Indian Ocean, was a failure. But the scientific results were more satisfying in the mass of observations of a physical, meteorological and astronomical nature done during the expedition.

As in Trondheim, the Danish society seems to have had an increasing interest in Danish history and language in the first half of the 19th century, embarking on publishing medieval sources, medieval history and medieval Danish language.

The Swedish academy seems to have taken another road, stressing their international contacts and partly also translating their writings to Latin, French or German, even though the majority of the articles published were originally and solely published in Swedish. The mighty secretary of the Academy, Jacob Berzelius (secretary 1818-1848), seems to have used his international reputation and network as a scientist to get the society as such involved in an international setting. Also, the annual report of the Society on the progress of sciences was followed with interest abroad, often being translated. One of the reasons for this was the reviews of recently published scientific works, which could be read for the information value, but also for entertainment –negative evaluation could be both quite merciless and eloquent.

* * *

To sum up: Several factors contributed to the decline of the participation in international networks of science in the post-Napoleonic era. One was that the wars themselves had uprooted the networks and partially destroyed some of the societies. Another, and perhaps more important, was the degree of specialization and the development of scientific disciplines to a degree that was not compatible to the notion of the all-rounder or gentleman amateur scientist. And third: It seems that the currents of nationalism and national romanticism of the mid 19th century made the societies more insular, preoccupied with aspects of national culture and history to a larger degree than before, and of communicating these interests basically to a national audience.

‘MOVED’ NATURAL OBJECTS –SPACES IN BETWEEN

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 488.

INTRODUCTION TO THE SYMPOSIUM

Marianne KLEMUN (organizer and chair)
Department of History, Group on History of Science, Universität Wien, AUSTRIA
marianne.klemun@univie.ac.at

A culture of natural history in the 18th and 19th centuries cannot be imagined without referring to objects or natural objects and their circulation. Closely connected to these are knowledge spaces, such as the cabinets of natural history specimens, the botanical garden and so on, that is, places into which natural objects are incorporated. Currently there is a boom in research in this area. This is primarily due to the history of collecting them, but also to cultural factors, and the history of knowledge and science.

However, in contrast to this focus, there will also be an emphasis on other spaces, which have so far not been recognized as independent research topics. These contexts, which we will here refer to as “spaces in between”, concern neither the collected object’s place of origin nor its destination. Actually, they are located between these two poles, between the starting point and the place of destination, such as a collection.

The topic is the movement of objects outside these points of reference. This “movement” may be of a variety of “natures”. It may change the “nature” of the objects themselves, change it into “culture” and make them different. What cultural practices are involved in these movement activities, and what significance is generated by these activities in different “spaces in between”, beyond the material basis?

Quite different phenomena may work as “spaces in between”, it may be a tent during a journey, a container, a packet transporting objects, as well as a letter and various kinds of records accompanying the objects. The question of how these lead us towards epistemic references will be discussed with the aid of a number of case examples.

GLOBAL TRANSPORTATION BY WAY OF SYSTEMIC TEMPORARY SPACES: SHIP, ISLAND, BOTANICAL GARDEN, PARADISE AND CONTAINER

Marianne KLEMUN
Department of History, Group on History of Science, Universität Wien, AUSTRIA
marianne.klemun@univie.ac.at

Abstract

In my contribution –looking at the world-wide transfer of plants that was established by botany in the 18th century– I am concerned with five 'spaces-in-between': ship, island, botanical garden, paradise and transport-container. For the 18th century I postulate a systemic relationship between these spaces, and I ask what effect this relationship had on the behaviour of the transport, on the one hand, and also on the dynamization of theories.

In the second half of the 18th century –because of the competition between European states– plant transfers mutated into a vital symbol for the world powers. This transfer was played out globally between 3 scientific spaces: between a ship, an island and a botanical garden. They are characterized not by their specific conditions, but they show themselves, rather, as instances of transfer.

The ruling elites of the early modern period loved exotic plants, admired them and brought them from distant places to Europe. At the same time the movement of plants from one part of the world to another, and over the oceans of the world, had moved to a new organized stage, particularly since it was taking place in the framework of a process of co-operation between science, the state and colonialism.[1] This co-operation also caused the movement of European institutions, such as botanical gardens, to tropical islands[2] (l'Île de France, then Ceylon and St. Vincent, to name only the first few.)

All three –ship, island and botanical garden– constituted spaces that were clearly distinguishable from one another and which formed a connective system for the 'travelling plants'. Island, ship and botanical garden certainly had something in

common with one another from a systemic point of view: they were culturally regulated and cognitively cut off from the immediate surrounding nature. In spatial terms they defined themselves by means of a constantly different dominating natural element. They rose markedly above their naturally determined environment, in that culturally they raised the internal in contrast to the external. In the same way as the instances of transfer (ship, island and garden),[3] the differently configured plant-transport containers –in spite of great variance– marked their isolation from their environment.

METAMORPHOSIS BETWEEN JUNGLE AND MUSEUM. COLLECTIONS IN THE MAKING

Kurt SCHMUTZER
ORF – Austrian Broadcasting Corporation, Vienna, Austria
kurt.schmutzer@orf.at

Abstract

Artistically preserved crocodiles, apes, piranhas and birds, intestinal worms conserved in alcohol –millions of specimens assembled in museums for Natural History around the world represent the outcome of numerous scientific expeditions since the mid-18th century. The zoological collections of Johann Natterer (1787-1843), gathered during his travels throughout Brazil in the years 1817 to 1835, give an excellent example to point out how specimens were moved from "jungle" to "museum" and how they changed on their way between these two spaces of knowledge.

Johann Natterer was a member of an expedition to Brazil initiated by the Austrian emperor Francis I and carried out by the imperial cabinet for "naturalia", the "Hof-Naturalienkabinett". Natterer was one of the many naturalists who made specimens available for scientific research, for classification and for display at the museum. His collections of Brazilian fauna are to this day a valuable part of the stock of the Museum of Natural History in Vienna. In collecting, Natterer and his superiors at the imperial cabinet saw the appropriate solution for their major scientific task, which was to bring order into the "realms of nature". Classification was their predominant concern.

Before individual animals became part of an exhibition or collection as a classic representative of its species, the specimens underwent several transformations. The animals were hunted, killed and skilfully preserved with the help of instruments and chemical means, denoted, described and placed in a system of natural-scientific nomenclature. The specimens were transported from continent to continent, they were passed on in international networks and at last they were displayed in museums or stored in collections for further studies, allocated within specific cultures of knowledge and "nature". Written and visual documentation both tried to verify these procedures and to secure reliable data for each specimen collected in distant parts of the world. Natterer's reports of his travelling and collecting in Brazil described these metamorphoses in question and at the same time they played an import role in this process.

These metamorphoses, produced by cultural practices like the art of taxidermy, altered the animals' physical composition and their appearance could only be maintained with the help of artificial means (preservatives, colours, artificial parts). But only the improvement in preserving animals in the late 18th century by using new chemical devices of preservation made it possible, that specimens could withstand long overseas transport. With the rise of taxidermy, a flow of manuals and guides for naturalists and taxidermists was published which helped to spread new methods and to popularize collecting and preserving practices.

Due to the many alterations, one can hardly relate to the specimens shown at the museum as being identical with or even being authentical images of the living animals. They are "made" cultural objects. When considering all these changes it may be surprising that the specimens' scientific values were not in question at the time of their acquisition. Despite all transformations and their artificial construction as cultural objects, the specimens were regarded as authentic representations of a species and –together with other information (sketches, reports, notes) – accepted as valuable and reliable sources for certain scientific questions. But dealing with historic scientific travels and collections has to take in account that a whole set of cultural practices was involved in creating the specimens displayed as seemingly authentic representations of "nature" in a museum's exhibition.

Abstract

Teodoro Monticelli (1759-1845), universally recognized by his contemporaries as the best of Vesuvius connoisseurs, was a man of science but also a man of power. He had been the rector of the University of Naples, and was at the centre of a wide and efficient network along which minerals, instruments and information had been circulating; but also scientific theories and new progressive ideas. This intense circulation is testified by Monticelli's correspondence.

Teodoro Monticelli (1759-1845), mineralogist, geologist, universally recognized by his contemporaries as the best of Vesuvius connoisseurs after the publication in 1825 of *Prodromo Vesuviano*, the first text of Vesuvian systematic mineralogy, in collaboration with his young pupil Nicola Covelli.[1] Man of science but also man of power, he had been the Rector of the University of Naples between 1826 and 1827, and had also been in touch with a large number of scholars inside and outside Europe; he was the centre of a wide and efficient network along which had been circulating minerals, scientific instruments and information: above all scientific theories, but also new progressive and democratic ideas. This intense circulation of things and ideas is testified by Monticelli's correspondence, a large number of manuscript documents very interesting for the history of science, the history of scientific institutions and collections, but also for social and political history.[2] From about two thousands letters received by Monticelli from his correspondents, emerge courses, directions and destinations of these movements. Generally, Monticelli established the relationships in the occasion of the visits to Vesuvius by these learned

[2] There are lots of biography about Monticelli, many information in E. MONTICELLI, *L'abate Monticelli*, Napoli 1932.

strangers coming from all parts of Europe.[3] Owner of a large and famous Museum of Minerals, Monticelli exchanged specimens of minerals from Somma-Vesuvius volcanic complex with the ones found in other parts of the world; he had also been selling, to a number of museums and private collectors, sets of Vesuvian rocks of an established cost and composition, found and arranged by a team of expert mineralogists he had specifically this job.[4] Thanks to this activity, the Natural History Museum of London still holds a rich Vesuvian collection, called Monticelli collection because it was bought from Monticelli with the intercession of Humphrey Davy, one of the leading scientists of the 19th century in Europe, President of the Royal Society (1820-1827) and one of Monticelli's closest friends.[5]

Davy met Monticelli during his first journey in Italy, in 1813. Here he had the opportunity to observe the eruption of Vesuvius of the days 25 and 26 December, and to analyze Vesuvian productions, as it clearly emerges from a short text written by Monticelli about this eruption and dedicated to Davy, who also invites him to come again to Naples and spend time together making further studies on Vesuvian activity.[6]

And Davy accepted Monticelli's invitation; in fact he was back in Italy and in Naples again in 1819, in 1820 and in 1825. In his third visit to Vesuvius, Davy met also Christian Frederic, Prince of Denmark later King Christian VIII, an interesting figure of modern and open minded sovereign, but also a true intellectual whose scientific interests went far beyond the usual limits of the 18th and 19th century amateur. In fact he also wrote some texts about Vesuvian phenomena and about the composition of rocks in Italy, Denmark and abroad.[7] During the winter of 1820, Monticelli, Davy and Christian Frederic spend some months in Sant'Anastasia, a little village in the Neapolitan countryside, hosted by the chemist of the place Pasquale Miranda, to observe directly and collect specimens of rocks, minerals and any other sort of volcanic products from the Somma-Vesuvius volcanic complex.[8]

Speaking about observations made in 1820, in particular Monticelli himself refers to an excursion made not only in the company of Davy and Prince Christian, but also with the famous French mineralogists Alexandre and Adolphe Brogniart, Giambattista Brocchi, one of the more representative Venetian scientists, and the Spanish Gimbernat, all of them to become his correspondents later.[9] This episode evidently shows how Vesuvius and Naples had been a true open air laboratory where anyone interested in Natural History had to go to try to complete his scientific education. In other words Vesuvius became a proper cosmopolitan open air laboratory in which the best natural philosophers in the world had been meeting, where Monticelli played a leading role not only in coordinating action and visits and in establishing contacts between scientist of any part of the world, but also in surrounding information and suggestions and hypothesis which in some cases were the basis of new theories. So the Neapolitan volcano was not just an interesting site in which 'to catch the nature on the fact',[10] but also a cultural centre, where Monticelli, as a proprietor of what Davy defines as 'il Vostro gran laboratorio vesuviano' ('Your big Vesuvian laboratory') had been hosting generations of scientists from all over the world considering him not only the best means to get up to the mountain but also a kind of interpreter of the secret language of the volcano.[11]

After the rather long period spent studying together in 1819, friendship between Monticelli and Davy became far stronger, as it is testified by the intense and affective correspondence in which Davy tried to avoid the English language that his Italian friend did not understand, and prefered a strange and rather incorrect Italian, or –rarely– French. In the years between 1819 and 1825, Monticelli also tried to involve Davy in the development of papyri of Herculaneum thanks to a new

chemical method he had invented and supposedly to more efficient than the old one of Padre Piaggio. Thanks to Monticelli Davy had the permission by the Bourbon Court to test his method upon some exemplars and also obtained some funds from the British Government for this job. But it seems that Davy never completed the task, maybe because of his new important and quite unexpected charge of President of the Royal Society, which leaved him truly few time for any other things.[12]

Notwithstanding Davy tried to help his Neapolitan friend to sell his Vesuvian collection to the British Museum, of which he was one of the trustees as President of the Royal Society. From the correspondence between Davy and Monticelli in those years, it clearly emerges how Monticelli decided to sell his collection both for economical and logistic problems. It seems he feared the loss of Palazzo Penne, maybe because he bought the ancient palace in which he arranged his mineralogical museum for a very small price from the State during the Napoleonic era. Davy tried to have the best price for the collection for his friend Monticelli, who made at least two sendings. The Monticelli collection is still preserved in the collection of Natural History Museum with the original Monticelli manuscript labels.[13]

Heir of a long and strong tradition, Monticelli's relationships with the United Kingdom –apart from Davy– where particularly strong.[14] In fact, John Herschel (1792-1871) himself appreciated this Neapolitan scholar, as he clearly said in one of his letters. Herschel was also the one who introduced Charles Babbage to Monticelli. In his Italian voyage, in June 1826, Babbage not only visited Vesuvius with him, but was so brave as to dare climbing up to the crater and exploringe the bottom of it, making some experiences which were discussed in the Società Reale Borbonica, of which he was appointed fellow correspondent.[15] So Monticelli got in touch with Lyell's ideas, which he very much supported, as he had met him when he eventually came in Naples in 1828, and as it was impossible for him to descend the crater directly, Monticelli offered him the sketches made on the spot by the Neapolitan landscape painter Antonio Siesto,[16] as it is confirmed by Lyell himself.[17] The images of the Vesuvius in its various phases were an essential part of the researches of this cosmopolitan group of scientists that usually brought with them artists to take pictures and simple drawings, or sometimes executed them themselves.[18] These art pieces, despite their aesthetic value, were collected and exchanged just to testify the shape of the carter or the main character of a precise eruption. In fact, Christian Frederic donated to Monticelli the original drawings made by his official painter, because the Prince thought that they would be useful for the scientific theories of his Neapolitan friend.[19] Two other close British friends of Monticelli were the Wilbraham sisters. In particular Hanna Wilbraham, later Grosvenor, good drawer and a smart and not banal geologist, is the author of some of the plates in Monticelli's text on the Eruption of 1827. The young woman long corresponded with Monticelli, adjourning him about more recent British theories on the origin of Earth, and in particular about Lyell and Babbage's gradualism.[20]

If Vesuvian minerals had been for years leaving Naples toward North Europe, on the other hand lots of equipments, coming above all from the United Kingdom and Germany, had been reaching Naples because Monticelli needed scientific instruments to study Vesuvius and its eruptions with modern means, and to adequate the scientific institution of South Italy to European standards. Among scientists sending him equipments, there was Alexander von Humboldt, who also played a major role in the diffusion of the gradualism and the central fire theories among Monticelli and his pupils. Humboldt esteemed Monticelli very much and appreciated his competence about geologic and Vesuvian matters; in fact, in one of his letters he asked the Neapolitan scientist a series of questions on the activity of Vesuvius and the variations of its shape.[21] A interesting document, where the long friendship between the two scientists clearly appears, was later published by Monticelli in one of his short reports on the volcano.[22]

Monticelli's network made him and his nearest pupils aware of the most modern scientific theories and technical discoveries, but it didn't really create a school of adjourned scientists. Reasons are probably political ones; in 1830 the death of Francesco I di Borbone, a still young and very well oriented sovereign, and then succession by his son Ferdinando, determined a drastic cut to the funds destined to the university and other cultural and scientific institutions, and so the situation began to get slowly but inexorably worse. In fact, 1848 was the year of the international congress of Italian

SCIENCE IN THE PUBLIC SPHERE: BARCELONA, 1868-1939

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 498.

THE EDISON TIN FOIL PHONOGRAPH IN BARCELONA: A DEMONSTRATION AT THE FREE ATHENAEUM OF CATALONIA (1878)[1]

Xavier VALL
Departament de Filologia Catalana, and Centre d'Història de la Ciència,
Universitat Autònoma de Barcelona, SPAIN
francesc.vall@uab.cat

Abstract

Thomas A. Edison and his phonograph (1877) attracted great admiration. On 12th September 1878, following its presentation in other European cities, a phonographic soirée for members and guests was held at the Free Athenaeum of Catalonia in Barcelona, founded that year, mainly as a reaction to the banning of positivist or Darwinist lectures at the Barcelona Athenaeum. The innovative firm Francisco Dalmau and Son imported phonographs (the first one from London for the School of Industrial Engineers of Barcelona) and experimented with them. Before Tomàs J. Dalmau presented the device at the Royal Academy of Natural Sciences and Arts of Barcelona, he participated in the phonographic session at the Free Athenaeum. This demonstration was preceded by a talk by the writer and science popularizer Joaquim M. Bartrina. Although many other activities, sometimes repeating the Bartrina-Dalmau tandem, took place at this centre, the phonographic demonstration contributed especially to its establishment as a leading institution for the local popularization of science and to the propagation of its views. Other scientists and amateurs were also interested in the phonograph, which was used at several locations, even in conjuring performances. This paper will analyse a case of the circulation and social exposure of technology in a context of ideological controversies.

The wide recognition of Edison and his phonograph, despite its less echoed precedents and its deficiencies, is proven by a large number of writings, in which some clues can be found. The phonograph, as a fulfilment of an obvious idea,

[1] This paper, which has been further developed in an article, was funded by the research project HAR2009-12918-C03-02, directed by Agustí Nieto-Galan. Among others, I am also grateful to the staff of libraries and archives. Lindsey Myhren and the language service of the *Universitat Autònoma de Barcelona* helped me with the English correction. Studies on Edison, the phonograph and its diffusion, the circulation of technology, scientific performances, the Catalan context... are very abundant.

could be used to endorse the positivist model and to promote trust in the great possibilities of technology, as well as contribute to its humanization.

This amazing invention quickly also became well-known in Spain, the state to which the largest part of the Catalan Countries belongs. In Madrid, on 10th December, a commentary about the phonograph, quoting *Scientific American*, is published by an engineer, according to the press and several studies, native of Catalonia (Alcover 1877: 355-356; see also 1878: 119; Fernández Bremón 1877: 354), and soon afterwards a lot of information, a large part of which has been forgotten, circulated about it around the Spanish State. Also in its capital, in the academic year 1877-1878 a phonograph was imported by the Saint Isidro Institute (Jiménez & Lastra 2006).

Of course, Edison became very popular in the Catalan lands as well (Glick 1983), in the context of considerable admiration towards the US, with which several relationships were established. For instance, a famous Catalan tongue twister ('*Setze jutges d'un jutjat*...') was soon recorded by a visitor to Menlo Park (Croffut 1878; http://edison.rutgers.edu; Israel, Nier & Carlat 1998: 213-220). Who was he? In any case, the engraving that illustrates the article was signed by 'Ph[ilip]. G. Cusachs'. This Catalan artist collaborated in the newspaper as well as *La Llumanera de Nova York*, which obtained an autograph from Edison (figure 1).

LA LLUMANERA

VOLUM VI. NOVA YORK, OCTUBRE 1880 NUM. 66.

Salut als lectors de La Llumanera

Thomas A. Edison

Fig. 1: A[rtur]. C[uyàs], 'Thomas Alva Edison', *La Llumanera de Nova York*, 66, october 1880, 1.
Biblioteca de Catalunya. Barcelona.
All images are reproduced with the kind permission of the libraries or archives mentioned.

It is said that on 21st February 1878 Francisco Dalmau and Son had obtained a five-year privilege for introducing the phonograph to Spain (Maluquer 1992: 123, and further studies by him; I am grateful for his response concerning this question). However, it has not been localized in the National Patents and Trademarks Office (Madrid), in the Cuban equivalent, among governmental dispositions or in the general and specialized press.[2] On the other hand, Edison had obtained the patent for the US only two days before, even though he had requested it on 15th December 1877.

In any case, *El Porvenir de la Industria* (157, 22/3/1878, 103) announced that Dalmaus' firm had received phonographic recorded sheets and expected that a phonograph would be delivered soon. It added that phonographs, which would be supplied in a few days, had been tested by their representative in London, and the plates recorded were displayed

[2] Other files about Dalmaus' inventions and the phonograph are conserved.

in Dalmaus' shop windows, at 9 Rambla del Centre, in Barcelona (160, 12/4/1878, 128), as the phonograph imported for the physics laboratory of the School of Industrial Engineers of Barcelona would be exhibited. Apart from other reports, the *Boletín Mensual de la Asociación de Ingenieros Industriales* (3, May, 11) informed that on 13th April this example was tested for the first time.

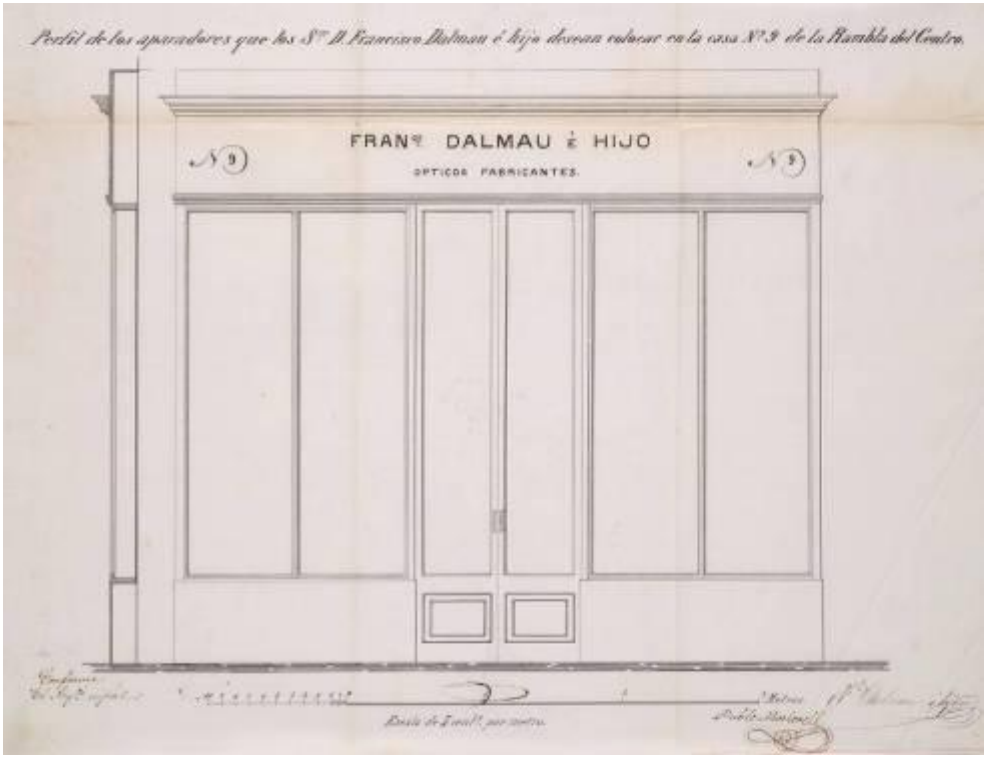

Fig. 2: Drawing for a renovation project of Dalmaus' shop windows,
at 9 Rambla del Centre, in Barcelona. 12th November 1873.
Arxiu Municipal Contemporani de Barcelona. Q127. Particular Works. *Foment*, file 2589-C.

Unfortunately, it is not conserved at the Higher Technical School of Industrial Engineering of Barcelona, where Lusa (2003) –whom, as well as Carles Puig-Pla and Antoni Roca Rosell, I thank for his help with research in this centre– unearthed a bill issued by Dalmaus' firm on 13th June, including a phonograph and phonographic plates. This would be the earliest phonograph in Spain, according to the press, as well as Suárez 1880: 461, an author studied by Sánchez Miñana, to whom I am grateful for his report on the status of his research on subjects related with this paper.

Josep Dalmau Montero (1956), the youngest son of Tomàs J., informed that he conserved part of the family heritage. Regrettably, it has not been preserved, according to some descendants. However, there is a large quantity of scattered information regarding the Dalmau family, which has been partially studied, as well as by economic historians (see also Cabana 1992), by historians of science.

Thanks to Sánchez Miñana and Lusa (2009, in addition to Sánchez 2006), we know that Francesc Dalmau was a musician from Manresa who became an optician in Barcelona. He had partners or collaborators, especially his son Tomàs J. and the engineer Narcís Xifra.[3] In 1881 Tomàs J. registered the Spanish Society of Electricity, becoming its managing director (see also Martín & Ollé 1961, García de la Infanta 1986, Altshuler & González 1998, Arroyo & Nahm 1994, Alayo 2007...).

The Dalmau family, despite their modest optician origins, imported, exported, manufactured, constructed, modified and invented many kinds of devices. I will only enumerate several activities: optics, photography, scientific instruments, lightning-conductors, electricity, illumination, telegraphy, telephony, industrial and agricultural machinery, armaments, electric bells...[4] A catalogue from 1877 was still well-known, but I discovered another from 1871 also at the Royal Academy of

[3] For more family details, see the files of his son Francesc de P. Xifra Montero and Manuel Dalmau Montero at the University of Barcelona.

[4] Several studies on some of these issues refer to the Dalmau family.

Sciences and Arts of Barcelona, significantly folded inside a secondary school textbook (Rico & Santiesteban 1864). There are also many advertisements in the press and in guides.[5]

Beyond marketing interest, they contributed to science popularization, through shows and writings. Moreover, they collaborated with societies, educational centres and professionals, for instance with doctors (Ausín 1999). Although Tomàs J. was a board member of the most important managers' association, *Foment* (minutes and the press), the Spanish Society of Electricity even earned the support of the anarcho-collectivist review *La Tramontana* (95, 13/4/1883, 3). The Dalmau family had a complex and important network of relationships and enjoyed great recognition in Spain, as well as obtaining certain acknowledgement abroad.

In 1874, finishing the Democratic Six-year Period, the Restoration began. However, the liberal substratum became apparent not only in political controversies, but also in scientific and philosophical ones, above all regarding positivism and Darwinism. One of the most important battlefields was the Barcelona Athenaeum. There, in 1877, the banning of lectures contributed to the constitution of the Free Athenaeum the following year.[6]

Having had its first site at 7 Rambla de Santa Mònica, it was relocated to 23 Avinyó Street (*Gaceta de Barcelona*, 109, 13/3/1878, 1581; *La Imprenta*, 72, 13/3/1878, 1764). There, on 12th April, an ode celebrating the 'inventor of the phonograph' was read (Roure 1878; *El Comercio de Barcelona*, 39, 13/4/1878, 513). What is more, on the evening of Thursday 12th September a phonographic session was held, following other European cities. This was considered to be the

[5] See also the documentation of the Municipal Contemporary Archive of Barcelona.

[6] See archives, minutes, the press and studies on Barcelona Athenaeum, some Free Athenaeum members and the reception of positivism and Darwinism.

first in Spain, even by Madrid press and Suárez 1880: 461.[7] Some details can be found in the Free Athenaeum printed memories, several evocations (such as Almirall 1880; Roure 1916, *s. a.*: 125-126; Dalmau, A. R., 1930) and multiple reports (one of which appeared in *La Academia*, 16, 30/10/1878, 254, illustrated with an engraving, 252 (figure 6), yet criticized by the *Gaceta de Cataluña*, 462, 5/11/1878, 2195).

Fig. 5: Caricature of the banning of lectures at the Barcelona Athenaeum.
Almanach de la Campana de Gracia. 1878.
Biblioteca de Catalunya. Barcelona.

Foreseeing a very large turnout, the soirée, which, unlike others, was only for associates and guests, took place in the largest room. In addition to the predominance of the society's ideology (with several tendencies), training levels were varied, from engineers (such as Manjarrés and Rojas) to people without scientific knowledge.

The act was opened by the writer Joaquim M. Bartrina (Reus 1850 – Barcelona, 1880), a science amateur and popularizer.[8] Having gained notoriety through the suspension of his lectures on pre-Columbus America (1881: 127-168) at the Barcelona Athenaeum, he was member of the board of the Fre Atheneum (sometimes as a secretary).[9]

We know that he was only enrolled in a few liberal arts courses at the University of Barcelona. However, he completed his training thanks to readings and contacts, evolving from romanticism to positivism, with a great dose of scepticism. He then worked at the *Gaceta de Cataluña* as an editor.

He wrote about multiple subjects, including scientific and technological topics, which are even present in his literary works. In addition to translating Darwin and applying his theories to several fields, his notes on physics are remarkable (Bartrina 1881: 270-288; 'Visión profética', *El Diluvio*, 145, 24/5/1916, 7; Ramon 1899; Roca [*s. a.*]: 19-21; Aguadé 1924...). Some of these would often be linked to the invention of the radio, yet this association had already been questioned. Without falling into exaggerations, Bartrina was far from being an ignorant visionary, since he had the support of the Dalmau family and information sources (from scientific studies to the general press). [10]

---

[7] The Free Athenaeum's session was omitted (Alier 1985; Barreiro 1992), as well as attributed to Barcelona Athenaeum (Lladó 1991 – probably misunderstanding Riutort 1946: 29–, quoted by Jones & Baró 1995: 32, and Gómez Montejano: 32). On the use of the phonograph as a show, see Feaster 2007.

[8] There are quite a lot of studies on him, but some issues have yet to be researched thoroughly. For instance, publications (such as early collaborations in *El Tesoro*), manuscripts, news, commentaries, imitations, parodies... have been forgotten.

[9] The manuscript of Bartrina's lecture is partially conserved with papers of Joan Sardà i Lloret, collector of his works (Bartrina 1881; Solà: 325), which at present are owned by his great-grandson Joan Sardà i Ferrer, whom I thank for providing access. Among them, I discovered manuscript fragments of 'La meteorología popular' (Bartrina 1881: 193-218).

[10] Among the books bequeathed by Bartrina's family to the Library of Catalonia, some are regarding these kinds of subjects, one of which, dedicated by Niaudet, is reproduced in figure 7. For more information about this and further Dalmaus' contacts, see Lusa 2003; Nieto-Galan 2003.

Example of the author of the paper.

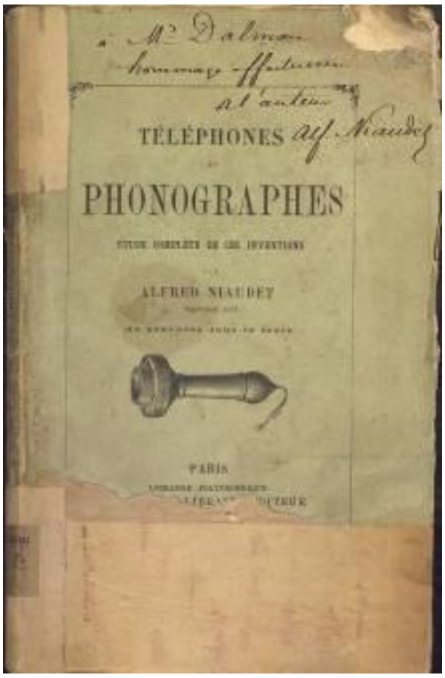

Fig. 7: Biblioteca de Catalunya. Barcelona. Catalogue number A 65-8-174. On pages 42-43, 'M. Dalmau from the academy of Barcelona', Tomàs J., is mentioned with regard to the telephone. The work was published for the first time in 1878.

Reports summarized that his presentation praised the American character, sketched Edison's biography in an anecdotal manner and described the device. Unfortunately, we do not have the text of his talk. Nevertheless, in addition to anonymous articles in the *Gaceta de Cataluña* about Edison and his phonograph, I found another similar to Bartrina's talk (A. T. O., 'L'inventor de fonògraf', *La Campana de Gracia*, 475, 15/9/1878, [1], figure 8). This pseudonym, the pronunciation of which sounds like the word 'Ateu' (in English, 'Atheist'), has already been attributed to him, as two articles from this review with the same signature were collected in his works (Bartrina 1881: 259-267).[11] The emphasis on Edison's self-education and the pun that the phonograph does not like 'capellans' (a word meaning not only 'a drop of saliva spat while talking', but also 'a priest') are the most remarkable issues.

Nevertheless, Bartrina considered that 'great discoveries often destroy statements considered *laws*' and, if Edison had respected them, some of his more notable inventions would not exist' (282). However, he thought that the phonograph and other devices were only 'primitive instruments' of 'the true physics', which 'in some centuries will turn into a science' (284).

Having yielded in part the role of speaker to Bartrina, Tomàs J. Dalmau began his experiments. In the same way as Edison and others conducted several testes with the phonograph and the phonographic sheets, at least, he used different materials for the membranes (steel, ivory and pine), positioned the device on top of a resonance box and substituted the clockwork mechanism by a Gramme dynamo. This association, although foreseeable, was attributed to Dalmau himself, who, as is well-known, had imported this machine. As Casas Barbosa ([1879]: 64) noticed, the dynamo improved the regularity of the mechanism, but it could not be a common solution.

After these experiments, the field marshal, Ramon Blanco, who had the support of progressive sectors and had already been present at the inauguration of the society, greeted the phonograph, as if talking to a person, in the name of the Free Athenaeum.

[11] Regarding his religious ideas, see, for instance, 'Rectificación y ratificación', *Gaceta de Cataluña*, 173, 12/11/1878, 2341-2342.

Then, musical recordings were made. Music, in addition to attracting the interest of some of the Free Athenaeum members, had become the most popular use of the phonograph. Along with literary and other recordings, several languages were employed with the aim of suggesting cosmopolitism: Catalan (one poem by the popular 17th century writer Francesc Vicent Garcia and an idiom), Spanish, Galician, Italian, English, and a dialogue in French and German.

The act was brought to a close with a speech by Bartrina expressing the Athenaeum's gratitude. According to the engraving, a Free Athenaeum member recorded a greeting to Edison. However, the press reported that the actual recording was made three days later at Dalmaus' workshop. The plate was kept in a case with a dedication in Catalan, and was exhibited in the clockmaker Wehrle's shop window. Regrettably, these objects are not conserved at the Edison National Historic Site, according to Paul Israel's and Leonard DeGraaf's kind responses.

Apart from some technical shortcomings, the event received wide exposure, except for the majority of the conservative press. The Dalmau-Bartrina tandem was repeated in other sessions, such as the presentations of the singing condenser and electrical light. Unfortunately, the society, which organized various activities, would disappear in 1882, for multiple reasons.

Dalmau and Bartrina also coincided at the Barcelona Society for the Protection of Animals and Plants, founded the same year as the Free Athenaeum. Moreover, at the time of the phonographic session, both were presided by the Darwinist doctor Joan Giné i Partagàs (the press).

We have abundant references to the phonograph in many fields. Anecdotally, on 28th December 1878, Saint Innocents' Day (equivalent to April Fools' Day), *La Crónica de Cataluña* (601, 2) even published the hoax that a supposed phonograph supplied by Dalmaus' firm was used at the Council of Barcelona.

Focusing on phonographic demonstrations, on 19th December 1878 and 15th January 1879, Tomàs J. Dalmau presented the phonograph and his modifications to it at the Royal Academy of Natural Sciences and Arts of Barcelona (file; minutes; a phonographic recording of the academics' names is conserved).

In April 1879 the phonograph was shown at the Romea and the Principal theatres, as well as in other Catalan cities, by the French conjurer Bargeon, who was criticized for this use of the device (Alier 1985: 345-346; Lloret 1998: 131; the press; Julian Romea's Society published a bulletin, in which some of Bartrina's poems were reproduced).

In the same month, in lectures on experimental acoustics by Rojas, he and Tomàs J. Dalmau demonstrated the phonograph at the Barcelona Athenaeum (Alier 1985: 346-347; minutes; the press). Rojas (1887) would publish an article on this device in a review, of which Edison appears as a collaborator, sponsored by the Spanish Society of Electricity.

On 3rd September 1879, Rafael Roig i Torres presented the project of his inscriptor phonograph, which, like the inventions of others, would record phonetic registers, at the conference of the *Association Française pour l'Avancement des Sciences* in Montpellier (minutes, Roig 1880ab, figure 10), obtaining certain exposure. He would have liked to show the phonograph and other instruments at the Circ theatre during the Mercè festival, yet, due to the lack of support, this was not possible. Nevertheless, in the next year's festival a phonograph and other devices from Dalmaus' firm were shown in Catalunya Square and probably the Jovellanos Theatre.

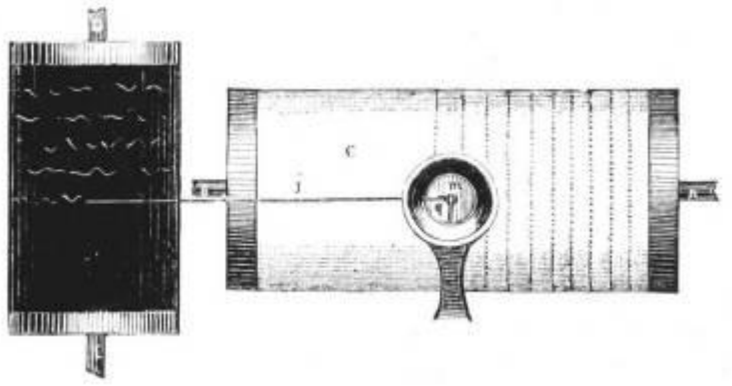

Fig. 10: Roig, 1880a, 228.
Biblioteca de Catalunya. Barcelona.

On 26th October 1880 Tomàs J. Dalmau still demonstrated the phonograph in a soirée organized by the Catalan Association of Excursions (minutes and the press) on the occasion of the Catalanist Congress.

During these years, the phonograph was also shown, often with the help of Dalmaus' firm, in other Catalan cities, such as, in 1879, Vic (Bernat 2010: 222), Mataró (at the Working Cooperative, by Xifra and Roig) and Pont de Vilomara (during its festivals, in a dancing marquee, also by Xifra); in 1880 and 1882, Reus (at the Reading Centre, respectively by Manuel Escudé and Àlvar Bielza), and, in 1881, Roda de Ter (during its festivals, at the Working Class Athenaeum). Of course the presence of the phonograph was increasing, rivalling other devices.

Although in 1880 an article possibly overestimated that the majority of laboratories had phonographs (Truillet 1880: 7) and the next year Dalmaus' firm did a stocktaking of five models (Historical Protocol Archive in Barcelona, notary Luis G. Soler y Pla, 27/4/1881, 1945), the majority of the public or private phonographic collections are from later or abroad.

It has been noted that the phonograph was also imported, constructed, innovated, explained, displayed and demonstrated in Barcelona and other Catalan cities and towns, emulating American and European modernity in a developing economy and contrary to political circumstances. Following an ancient link between science and performance, this device was presented by people from different backgrounds (in general, technicians, but also a writer and a conjurer) to various audiences in several sites (shops, schools, cultural centres, academies, clubs, cooperatives, theatres, fairs, dancing marquees...), on multiple events (specific displays, lectures, performances, festivals, political conferences...). 'Appropriation' (in the meaning established, with precedents, by Roger Chartier) could be spoken of, at least to the extent of using the phonograph to a certain juncture, with the aim of, over and above promoting technological progress, obtaining recognition and ideological acceptance. The analysis of this local case, supplying much previously unknown information from primary sources, illustrates, as well as some general possibilities regarding the circulation of technology, that, if environments are studied thoroughly, a richer scientific and social situation also emerges in the periphery.

THE CONSTRUCTION OF GROUP THEORY IN CRYSTALLOGRAPHY

Bernard MAITTE
CHSE (Centre d'Histoire des Sciences et d'Épistémologie) – STL («Savoirs, Textes, Langage»), Université de Lille 1, FRANCE
bernard.maitte@univ-lille1.fr

Abstract

The French molecular approach led to the distinction of fourteen types of lattice system, while "Naturphilosophie" can count 32 classes of symmetry. At the end of the century, the mathematical study led to 230 different groups belonging to 32 classes, 14 networks and 7 systems.
In this paper, I will show how, in the continuity of the founding works of Romé de l'Isle (1772) and René-Just Haüy (1801), introducing a triperiodic crystalline structure composed by "integrant molecules" filling the space (7 systems), Gabriel Delafosse (1843) introduces the concept of the crystal lattice repeating "polyhedral molecules" which do not fill the space.
This view helps explain the "notable exceptions" to the "law of symmetry" of Haüy (the "mériédries"). This approach is generalized in 1848 by Bravais in his study of "systems composed by systems of points" (enumeration of 14 modes of networks ").
Meanwhile, the German crystallographers, based on continuous view of matter characteristic of "Naturphilosophie", describe attractive and repulsive forces fighting in space.
From this idea, they induce the concept of the "axes of symmetry" (Weiss 1805). The combination of these elements of symmetry concurring, discussed by Weiss, continued by Mohs and Hessel, leads in 1830 to the counting of 32 "classes of symmetry".
The combination by Sohncke of networks and those of classes that he knew would lead to the enumeration of 61 various "groups of space" (1879). It is with an entirely mathematical approach, without figure, introducing elements of non-concurrent symmetry and introducing the problem of the regular partition of the sphere, that Fedorov and Schoenfliess manage to count, independently of one another, 230 groups of symmetry (1891).
The determination of groups of space is now complete. It can bring together the concepts of systems, classes and types of networks. The "groups", counted without reference to ideas of Galois and its successors, will play an essential role in physics after the work of Pierre Curie (1894).
It's a whole century of efforts from crystallographers working in various contexts and with different pre-supposed that I retrace.

The history of the construction of Group Theory in crystallography extends over two centuries. It crosses diverse branches of science (natural philosophy, physics, mineralogy, crystallography, chemistry and mathematics), and develops varying characteristics depending on the geographical or cultural backgrounds concerned. Different scientific traditions are set in motion giving rise to the use different methodologies. In the 17th century it is Kepler[1] and Hooke[2] who, amidst the fever of observations and interpretations typical of the birth of a "new science", study with both the naked eye and under microscope regular crystal forms and attempt to explain them through a subjacent structure which remains inaccessible to the best instruments at their disposal. Their efforts are taken up by Christian Huygens[3] who contributes to the creation of a profane, geometric and "hypothetical-deductive" science, based on mechanisms which apply in the world of Descartes: a world filled by an infinitely liquid ether, composed of elements comparable to hard spheres, in contact with one another. He observes calcite, its patterns, its cleavages and birefringence, and shows that all these properties possess a common symmetry. He represents them as a triperiodic assemblage underlying ether-immersed molecules, a structure which slows down the speed of passing light waves. He deduces various physical properties from this hypothesis, which are not yet perceived, but are to be so soon, and accurately predicts the numerical consequences which he verifies through experiment. The development of this rich approach is however brought to a halt by Isaac Newton, partisan of an empty world of discontinuous matter, of a corpuscular theory of light, a Newton who makes full use of his authority, and of false measurements, to discredit it[4].

It is in fact much later, and independently to the work of its precursors, that the history moves forward. It is linked to the Enlightenment, the century of such a prodigious effervescence, inspired by Locke and Malebranche. For them, the "great systems" of mechanics are incomplete: gravity can only be explained, according to Newton, through theology, and life cannot be accounted for merely by a machine. For Locke (1690), human understanding emanates from two sources: on the one hand external objects which provide qualities, and on the other hand perceptions and the mind which supply him with ideas. To increase knowledge, it is necessary to discover significant properties. If the definition of a world system remains the objective, it is an ideal that cannot be achieved without patient analysis. From that point, the focus must be on empiricism and finding in our non-mechanical reasoning new channels for science. The 'truth' is only the temporary matching of all our discoveries. Applying this limit to knowledge guarantees tolerance. Savants and philosophers, deists and atheists, study with passion all that had been neglected by the great systems: polyhedrons, electricity, magnetism, nature and life. The history of natural science becomes a moment in the history of all sciences, a history that is written in parlours, in the "cabinets de curiosité" where naturalists expose their findings or their purchases from their various excursions, and attempt to classify them, turning their attention to crystals. Romé de l'Isle wants to determine their significant properties: he turns his attention to the outer pattern of crystals. To classify them he measures, and notes:

> *"Although the faces of a crystal can vary in their shape and their relative dimensions, the respective inclination of these same faces is constant and invariable across all types."*[5]

It is *the first law of crystallography* (1772).

To explain this "constancy of angles" represented by idealised patterns of crystals, Romé de l'Isle considers them as assemblages of parallelepiped invisible to the microscope, possessing all the qualities of macroscopic crystals, filling space: "integrant molecules". He describes their possible forms and founds what he rightly considers to be a new science – crystallography[6].

Shortly afterwards, another French naturalist, René-Just Haüy carries out the same studies. He silences Romé de l'Isle's precedence and invents the tale of a chance discovery to explain that calcite always cleaves identically, and that it results from the triperiodic assemblage of «molecules intégrantes». In 1784, Haüy abandons the idea of *"establishing crystallography along fixed principles*": the physical and chemical properties of crystals are too diverse. *Forms can only be used in a subsidiary manner*[7]. In 1792, Haüy's studies are completed and diversified. His attention to patterns grows stronger: physicians and mathematicians (Laplace, Monge) show interest, noting to their great satisfaction that geometry can be applied even to natural science[8]. In his 1801 work on Mineralogy, *Traité de minéralogie*, Haüy sets out to describe all the

properties of minerals and to classify them[9]. He writes: *"Physics, Chemistry and Geometry … must advance hand in hand along the same route…"* He classifies according to Chemistry, but attaches great importance to patterns: he organises them in six «primitive forms». This enables him to explain the inclination of sides by «truncation» of these patterns according to rational factors, and to explain the absence of regular pentagons in nature by the total filling of space.

In the «Comparative Table of… crystallography and chemical analysis…» (1809), Haüy changes his stance. He writes: *"Chemistry gives us applications; crystallography allows us to distinguish between types… It is only in geometry where all minerals are pure."*

He concludes his work in 1815[10], then in 1822, with his law of symmetry which generalises all his deductions: If the face of a primitive parallelepiped undergoes a certain reduction, or remains identical, the other analogical sides will undergo the same reduction or will remain identical… The same applies to angles. Haüy adds: *"I can prove that it is crystallography that rules the distinction of types and not chemistry*". But some crystals present tetrahedral shapes which do not obey his law. These are considered by Haüy as marvellous exceptions…

It is just these exceptions that German crystallographers set out to explain. Building on Haüy's work, and above all following the tradition of "Naturphilosophie", principally developed by Kant[11] and Schelling[12], they refuse at the beginning of the 19th century the molecular concept of matter. They prefer the theory of continuous matter, divisible to infinity, a space in which reside antagonistic forces, attractive and repulsive, occasionally reaching equilibrium. The place at which the points of equilibrium are reached is a crystal face. Homologous faces are produced by analogous forces, organised along convergent lines. Those with equivalent symmetry correspond to "axes of symmetry", a new concept introduced by Weiss[13]. He defines several convergent axis compatible to crystals, combines them and defines the symmetrical classes, grouping them in crystal systems. Haüy's exceptions are explained by these classes. In 1822, Friedrich Mohs[14] corrects some of Weiss' errors and distinguishes six (seven) crystal systems, whilst in 1830 J.F.C. Hessel completes his predecessor's approach[15]. He defines the direct and inversed axis compatible with crystals, combines them in all possible manners, shows that there can only be 32 classes of symmetry, spread over six (seven) systems. And yet this work is to be ignored for some time to come.

The results obtained in Germany are deliberately ignored by French mineralogists. They are unable to accept the introduction of axis of symmetry, which they could perhaps consider as lines of molecules, but which remain in their minds as vague and incomprehensible philosophical notions. Delafosse and Durozier write:

> *"[German] Mineralogists [are] hostile … to … the … molecular theory [the cause of which needs to be examined]… in the idealist theory: this type of metaphysical consideration which preoccupies all German intellectuals. A few ambiguities taken from the Greeks, a few fallacies based on Kant's contradictions, have led the German physicists to prefer in the study and interpretation of natural phenomena the sort of vague and obscure explanations that they call "dynamic" rather than the simple clear and positive notions that we draw from atomistic hypotheses."*[16]

In 1840 Delafosse takes up Haüy's research, regretting that he did not *"give to his work the character of a theory of physics"*, and explains the "marvellous exceptions" within a newtonian framework, by imagining that molecules of which crystals are constituted are of polyhedron form and repeat themselves in networks[17]. This lattice concept is assured a bright future: in 1848 Bravais lists 14 possible modes, classified into the seven systems[18]. He limits his speculation to "purely geometrical speculation", wishing to protect his work from relying on a newtonian vision of matter at a time when this concept is brought more and more into question. As soon as the following year, however, he applies his networks to crystallography

and is the first in France to introduce axis of symmetry[19]. But it is a German, Sohncke, who extends the interest of the use of lattices through the combination of systems, classes and modes, and he inventories what we call the "*Sohncke groups*"[20]. The identification of groups in crystallography is not yet over. Fedorov introduces elements of symmetry with translation and sliding which leave lattice types invariable[21].

Setting out to achieve a formal mathematic study, he can show that (independently and simultaneously as Schönflies[22]) there are 232 sub-groups in the groups, the classes, the modes and the systems. It is to be noted that all the group plans are represented in the decorative patterns of the Alhambra in Granada (14th Century).

Reflexion on the approach of these crystallographers leads Pierre Curie[23] to take things one decisive step further: no longer limiting it to shapes and the study of forms, but considering symmetry as a reasoning tool, in which form becomes mentally integrated and generates ideas. This will allow the notions of invariants to evolve, which will be greatly used in classical physics, and later at the onset of relativity and quantum physics. The use of groups in Symmetry will also allow the birth and subsequent development of crystallography. In 1912, Von Laüe wants to check both that X-rays are electromagnetic waves and that crystals are networks. Placing a crystal in front of an X-ray source, he obtains diffraction effects. After the work of Debye (1924), it appears that these diffractions can be interpreted using the 230 groups. It is their first practical elucidation, 35 years after their enumeration.

ON THE BIRTH OF ELECTROMAGNETIC THEORY. FARADAY AND MAXWELL

Raffaele PISANO
Centre François Viète, Université de Nantes, FRANCE
pisanoraffaele@iol.it

Abstract

In the 19th century, a complex system of approaches, models, and theories circulated. In order to interpret mathematically any kind of motion by means of central forces –differential equations–, a mechanical scientific program was presented by Laplace (1749-1827) in Traité de Mécanique céleste *(1805). Fourier (1768-1830) proposed a strong mathematical approach by differential equations (1807; 1822) without considering nature of heat and experiments. For new fields of electricity and magnetism phenomena, Ampère (1775-1836) also presented a mathematical approach (1820; 1828) based on previous Ørsted's (1777-1851) experiments (1820); latter showed that new and non-mathematical interaction, outside of mechanical foundations, could be observed. In this view, the lack of infinitesimal analysis in Sadi Carnot's (1796-1832) theory (1824), in Ørsted's works and in Faraday's (1791-1867)* Experimental Researches in Electricity *(1839-1855) are emblematical expectations. Particularly, Faraday –without any formula– introduced the basis for the concepts of field and vectors in electromagnetic induction theory. After the second half of the 19th century a mathematical approach still strongly emerged. Stressing the mathematics-physics relationship, many theories were included in mechanics becoming new «rational-analytical» theories, where principles «ne présuppose aucune loi physique» and experimental studies were not in attendance. E.g., in the wake of Fourier, propagation, velocity applied, etc… was proposed (1861) by Lamé (1795-1870). In late (electrothermal and) electromagnetic theory an advanced use of mathematics was presented (1864-1873) by Maxwell (1831-1879) to mechanically explain («vortex») new Faraday's phenomena by means of a unique mathematical scheme described by his four equations. Even if he frequently claimed that his work (*Treatise*) is a mathematical interpretation of Faraday's physics, the approach was strongly different: abstract concepts and new mathematical problems. The four equations and Lorentz's law essentially completed the classical electromagnetic theory.*

MATHEMATICAL PHYSICS IN ITALY IN THE 19TH CENTURY: THE THEORY OF ELASTICITY

Danilo CAPECCHI
Università di Roma *La Sapienza*, ITALY
danilo.capecchi@uniroma1.it

Abstract

In the second half of 19th century there was in Italy an important group of mathematicians busied with mathematical physics. The most prominent of them are Enrico Betti (1823-1892), Eugenio Beltrami (1836-1900), Gregorio Ricci-Curbastro (1843-1925), Valentino Cerruti (1850-1909) and others, whose activity will persevere for many years in the 20th century: Vito Volterra (1860-1940), Carlo Somigliana (1860-1955) and Tullio Levi Civita (1873-1941).

In the paper I speak of the contribution of this group to the theory of elasticity.

Probably the best representative writing on continuum mechanics and elasticity as mathematical physics theories is the book Teoria della elasticità *by Enrico Betti (1872-1873). The book is interesting not only for the particular results found but also, may be mainly, for its framework which will become paradigmatic for the development of subsequent texts on elasticity, not only Italian.*

During the 19th century in Europe the gap between mathematics and physics was already becoming large. Mathematicians were concerned with the 'new' mathematics in the attempt to make it more rigorous and to solve some theoretical problems; physicists were instead mainly concerned with experimental activities. In this context a new branch of learning emerged, now called *mathematical physics*. It originated from some physical problems formulated by means of complex mathematical relations which needed to be solved with such a mathematical skill to be in possession only of mathematicians. Most of them were not interested in the physical aspects of the problems, but only in developing daring mathematical theories which had physical repercussions at most as a secondary scope. This trend became more pronounced towards the end of the century.

Italy followed Europe, even though with some delay. The general scientific level in Italy, at the end of the 18th century was quite low; this was true for mathematics too. During the Napoleonic period things changed. In particular, in the *Istituto nazionale* of Bologna, by means of Vincenzo Brunacci, the new mathematics reached very enthusiastic people that in the following were able to spread mathematics and mathematical physics into Italy.

Vincenzo Brunacci (1768-1818) was a follower of Lagrange. He became professor of mathematics in 1790 at the *Scuola marina* in Livorno and in 1798 published his first relevant work, *Calcolo integrale delle equazioni lineari* (Brunacci 1798). During the Napoleonic period he was member of the *Istituto nazionale* and rector of Pavia University. After a short period of banishment in Paris he came back to Pisa in 1800 and since1801 was professor of *Matematica sublime* in Pavia.

Brunacci transferred his ideas to his students, among which Antonio Bordoni, Fabrizio Ottaviano Mossotti and Gabrio Piola, the most brilliant mathematicians of the first half of the 19th century. Bordoni was an academic and succeeded Brunacci in the chair of mathematics in Pavia; Mossotti after some vicissitudes set up as professor of physics in Pisa; Piola followed a more private path.

Brunacci is then at the top of a genealogy collecting all the greatest Italian mathematicians, in a more or less direct way. In Milan: Piola, Brioschi, Tardy; in Pisa: Mossotti, Betti, Dini, Arzelà, Volterra, Ricci Curbastro, Enriques, etc.; in Pavia: Bordoni, Codazzi, Cremona, Beltrami, etc. (Pepe 2007).

* * *

In the second half of the 19th century there was in Italy an important group of mathematicians busied with mathematical physics. The most prominent of them were Enrico Betti, Eugenio Beltrami, Gregorio Ricci-Curbastro and some others whose activity persevered for many years in the 20th century: Vito Volterra, Carlo Somigliana and Tullio Levi Civita. In the paper I speak of the contribution of this group to the theory of elasticity.

Probably the best representative writing on continuum mechanics and elasticity as mathematical physics theories was the book *Teoria della elasticità* by Enrico Betti. The book is interesting not only for the particular results found, but also, even perhaps mainly, for its structure which became paradigmatic for the development of subsequent texts on elasticity, not only Italian. Betti's interest is concentrated on the mathematical aspects of a physical theory. Physical principles are not discussed, but only exposed in the most formal way possible. The objective is to arrive, without discussing epistemological or empirical problems, to the formulation of differential equations which rule elasticity.

Beltrami has written no complete books on elasticity, but his contribution to this field was perhaps more original than Betti's. A similar discourse holds true for Volterra and Somigliana.

THE MATHEMATICAL PHYSICS IN THE STYLE OF GABRIEL LAMÉ: THE ADVENT OF THE «PHYSIQUE MATHÉMATIQUE» IN EMILE MATHIEU'S TREATRISE

Evelyne BARBIN[1], René GUITART[2]
[1]Centre François Viète, Université de Nantes, FRANCE
evelyne.barbin@wanadoo.fr
[2]IMJ – Institut de Mathématiques de Jussieu, Université Paris 7 Denis Diderot, FRANCE
rene.guitart@orange.fr

Abstract

As a resumption of Poisson's project of a complete his Traité de Physique mathématique*, Lamé provided an introduction to* Physique mathématique *through a series of papers in the period 1830-1840, and later in four books edited between 1852 and 1861. In the introductions of these books he explained that the* Physique mathématique *has been a creation of the beginning of the 19th century, by men like Laplace, Fourier, Fresnel, Poisson, Cauchy. He strongly claimed for the unity of pure and applied mathematics. He emphasized on the technical unity of mathematics for physics, because there is always almost the same equation to solve: Poisson's or Laplace's equation. At the level of the explanation of phenomena, another unit has to be associated to this technical unity: for Lamé it is the existence of aether. His main technical inventions are the calculus of curvilinear coordinates and especially with ellipsoidal coordinates, and his famous 'Lamé's equation', deeply studied by Hermite later. Lamé's project was re-opened by Mathieu, in some sense a student of Lamé, which put explicitly his work (entitled Traité de Physique mathématique) under the patronage of Fourier, Poisson and Lamé.*

In his paper *Emile Mathieu, his life and works*, Pierre Duhem wrote: «The death of Lamé resulted in finally bringing mathematical physics into discredit in France». But nevertheless we can ask if really, with Lamé, or perhaps finally with its true successor in physics, Emile Mathieu, something is accomplished or finished, under the name of *Physique mathématique.*

In the beginning of the 19th century, Simeon-Denis Poisson had the project of a complete *Traité de Physique mathématique*, with his *Traité de mécanique*, 2 vol. (1811), as an introduction, and with chapters on capillarity (*Nouvelle théorie de l'action capillaire* (1831)), on heat (*Théorie mathématique de la chaleur* (1835)), on elastic bodies and fluids. But this vast project was not achieved. Let us insist on the opinion of Poisson saying that: «l'Analyse pure n'est point le but, mais l'instrument; les applications aux phénomènes sont l'objet essentiel» (Hermite, *Discours à la Sorbonne*, 1889).

Lamé himself provided a kind of introduction to the *Physique mathématique* through a series of papers in the period 1830-1840, and then with four books: *Leçons sur la théorie mathématique de l'élasticité des corps solides* (1852), *Leçons sur les fonctions inverses des transcendantes et les surfaces isothermes* (1857), *Leçons sur les coordonnées curvilignes et leurs diverses applications* (1859), *Leçons sur la théorie analytique de la chaleur* (1861). In the introductions of these books he expressed his opinion that the *Physique mathématique* was a creation of the beginning of the 19th century, by men like Laplace, Fourier, Fresnel, Cauchy.

He also strongly claimed for the unity of pure and applied mathematics, of both theory and practice. But mainly, he wrote on the unity of mathematics for physics, on the fact that for a large variety of problems we have always more or less to solve the same equation; that is Poisson's or Laplace's equation. To this unity at the level of analytical computations, something has to be associated at the level of the explanation of phenomena: for Lamé it is the fact that aether exists. His main technical contribution is the calculus of curvilinear coordinates and especially of ellipsoidal coordinates. In this setting, the examination of the question of the separation of variables led to the famous Lamé's equation, deeply studied by Hermite later.

Lamé's project was re-opened by Emile Mathieu, in some sense a student of Lamé, which put explicitly his work, entitled *Traité de Physique mathématique*, under the patronage of Fourier, Poisson and Lamé. Mathieu gave a *Dynamique analytique* (1878), with a purpose similar to the one in Lagrange's *Mécanique analytique* or Jacobi's *Vorlesungen ûber Dynamik*. In fact, it is explicitly proposed as a sequel to Lagrange. As a prolongation of Poisson's project, and with the help of the works of Lamé, Mathieu also developped a *Traité de Physique mathématique*, including: I -Cours de physique mathématique (1873); II -Théorie de la capillarité (1883); III and IV -Théorie du potentiel (1885), Applications à l'Electrostatique et au magnétisme (1886); V -Théorie de l'électrodynamique (1888); VI and VII -Théorie de l'élasticité des corps solides (1890). In the introduction of his *Cours de physique mathématique* (1873), he wrote that the "physique mathématique" is a branch of mathematics mainly created by the works of Laplace, Fourier, Poisson and Lamé.

THE INTERACTION OF PHYSICS, MECHANICS AND MATHEMATICS IN JOSEPH LIOUVILLE'S RESEARCH

Jesper LÜTZEN
Department of Mathematical Sciences, Københavns Universitet, DENMARK
lutzen@math.ku.dk

Abstract

According to Joseph Liouville, mathematics owes its most important progress to physics, and in particular to mechanics. In fact, many of his own most important research was directly or indirectly inspired by physical problems. In the talk I shall exemplify the physical origin of some of Liouville's theories and results. Some of them are surprising. For example, it is rather surprising that his theory of differentiation of arbitrary order (fractional calculus) was a result of his attempt to find elementary forces in a Laplacian approach to physics, and that his celebrated theorem about the constancy of volume in phase space was inspired not by thermodynamics but by perturbation theory in celestial mechanics. I shall also show the close link existing between Liouville's research in mechanics and his research in differential geometry.
The talk will exemplify the close links between mathematics and physics in France at the beginning of the 19th century.

In a brief biography of Joseph Liouville (1809-1882) his former student Herman Laurent recalled:

> I have often heard Liouville say that it is to the study of natural phenomena and in particular to mechanics that mathematics owes its most important developments, and this truth certainly manifests itself in the memoires of this illustrious mathematician (Laurent 1894 p. 132).

Indeed, Liouville contributed to the following areas of physics:

1. Electrodynamics
2. Heat
3. Various subjects of mechanics:
    a. Rotating masses of fluid
    b. Hamilton-Jacobi mechanics
    c. Potential theory (gravitation and electrostatics)

Moreover his contributions to the following areas of pure mathematics

4. Differentiation of arbitrary order (fractional calculus)
5. Sturm-Liouville theory
6. Geometry

were directly inspired by physics. Let me exemplify some of these interactions:

3a. The shape of a fluid rotating planet had been a major question since the time of Newton. Maclaurin had shown that it could be an ellipsoid of revolution and in 1834 Jacobi announced that also three axial ellipsoids could be equilibrium figures. Liouville studied how these figures depend on the angular momentum of the planet, and discovered that for a momentum for which both types of ellipsoid exist, it is Jacobi's three-axial ellipsoid which is stable. He proved these results using new formulas for the so-called Lamé functions and later showed how these formulas can be used to solve Gauss' version of the Dirichlet problem for an ellipsoid. Moreover he observed that he could generalize this method to arbitrary closed surfaces, if he replaced Lamé functions by another system of "orthogonal" functions that are eigenvalues of a certain integral operator. He did not publish this theory, but it anticipated many results concerning integral operators by at least 40 years.

4. Liouville's theory of differentiation of arbitrary order (i.e. of operators of the form $(d/dx)^a$ where *a* can be an arbitrary complex number) grew out of his work with Ampère's electrodynamic theory and more generally from the fundamental question in Laplacean physics: From observed macroscopic forces to determine the microscopic fundamental force law that will give rise to the observations. Liouville pointed out that this question can be formulated as an integral equation, and he discovered that such equations can in many cases be solved using derivatives of non-integer order. This made him develop a theory of such generalized differential operators.

5. Sturm-Liouville theory grew out of physical problems concerning heat conduction and vibrations.

6. Finally, Liouville's famous theorem according to which any conformal mapping from space into space can be composed of similitudes and inversions in spheres was developed as a result of collaboration and correspondence with William Thomson (later Lord Kelvin) about Thomson's method of electrical images in electrostatics.

THE EMERGENCE OF MATHEMATICAL PHYSICS AT THE UNIVERSITY OF LEIPZIG

Karl-Heinz SCHLOTE
Sächsische Akademie der Wissenschaften zu Leipzig, GERMANY
schlote@saw-leipzig.de

Abstract

Mathematical physics became a prominent discipline at the University of Leipzig due to C. Neumann and K. von der Mühll in the second half of the 19th century. However, this blossom of mathematical physics caused also a delay in the development of theoretical physics. A professorship for theoretical physics was not established until 1894. In the talk I discuss this development as well as Neumann's views to mathematical and theoretical physics. A comparison of this development with those at other universities reveals interesting differences in the process of establishing theoretical physics in the physics department. Neumann's opinion about mathematical physics played an important role in the discussion about the characterization of mathematical and theoretical physics.

Looking back upon the history of mathematics at the University of Leipzig, we can state a long lasting tradition of mathematical physics. Mathematicians like August Ferdinand Möbius (1790-1868), Carl Neumann (1832-1925), Leon Lichtenstein (1878–1933), Ernst Hölder (1901-1990), Herbert Beckert (1920-2004) or Paul Günther (1926-1996) were representatives of this tradition. The investigations below are concentrated on the upswing of mathematical physics at the end of the 1870s and Carl Neumann's role in this process. The upswing was mainly caused by the appointment of Neumann as full professor of mathematics in 1868 and the appointment of Karl von der Mühll (1841-1912) as lecturer for mathematical physics at the beginning of the same year. Both had attended the famous mathematical-physical school at the University of Koenigsberg and received their doctorate at that university in 1856 and 1866, respectively. Problems in mathematical physics, in particular in electrodynamics, and potential theory became the dominating topics in Carl Neumann's scientific work. Besides the treatment of concrete physical problems Neumann developed and shaped his methodological view on mathematical physics that he realized in several of his investigations. He took the opportunity of describing his views on mathematical physics in his inaugural lectures at the universities of Tubingen and Leipzig in 1865 and 1868. He formed a picture of mathematical physics in his work that was coined by mathematical aspects. However, he overestimated a high mathematical level as a criterion for the quality of a physical theory. This made it difficult for him to incorporate new physical ideas into the explanation of physical phenomena in his own research.

The blossom of mathematical physics at Leipzig University caused a delay in the foundation of theoretical physics at its physical institute. The first upswing of theoretical physics in Germany that took place in the 1870s and 1880s was missed by the Leipzig physicists. The first professor for theoretical physics was appointed at the University of Leipzig only in 1894. It was Hermann Ebert (1861-1913), who became an extraordinary professor but was followed by Paul Drude (1853-1906), an outstanding theoretical physicist, in the same year. Due to Drude's activities, the backlog in the development of theoretical physics was caught up within a few years.

CHEMICAL ORDER IN TRANSIT: COMPARATIVE STUDIES OF THE RESPONSE TO THE PERIODIC SYSTEM

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 525.

THE RECEPTION OF THE PERIODIC SYSTEM IN DENMARK

Helge KRAGH
Department of Science Studies, Aarhus Universitet, DENMARK
helge.kragh@ivs.au.dk

Abstract

In this essay I examine how the periodic system or table was introduced in Denmark in the late nineteenth century, how it was used in chemical textbooks, and the way it was developed by a few of the country's scientists. I pay particular attention to the work of Julius Thomsen, which is an important example of neo-Proutean attempts to understand the periodic system in terms of internally structured atoms. Moreover, I direct attention to Mendeleev's connection to Danish science by way of his membership of the Royal Danish Academy of Sciences and Letters.

Early discussions of the periodic system

The first published recognition of the periodic system among Danish chemists dates from 1880, when the young chemist Odin Christensen reviewed the recent discoveries of chemical elements, including gallium and scandium. In this connection, he discussed the new elements' place in "the system", such as predicted by Mendeleev in the form of the hypothetical elements eka-boron and eka-aluminium. He concluded that gallium and scandium "provide strong support in favour of the view of Mendeleev, namely, that the properties of the elements and the constitution of their compounds are periodic functions of the atomic weights of the elements."[1] Christensen further noted that Emile Lecoq de Boisbaudran's discovery of gallium had taken place wholly independently of Mendeleev's prediction, which he found to be further confirmation of the essential truth of the periodic system.

Christensen was evidently impressed by the agreement between the predictions of Mendeleev and the metals discovered by Boisbaudran and Lars Frederik Nilson. Yet another triumph of Mendeleev's law was the outcome of the controversy concerning the correct classification of beryllium, as a homologue of either magnesium or aluminium. Based upon the law of Dulong and Petit, its atomic weight came out as approximately 14, a value which indicated that beryllium was a tervalent element, in disagreement with Mendeleev's conclusion. Only about 1880 was the element's atomic weight determined to 9.1, which largely settled the controversy. As Christensen saw it, the problem had been solved, with the new atomic weight being a "proof of the great significance that must be ascribed to Mendeleev's periodic law."[2]

---

[1] Christensen 1880, p. 421. On the significance of Mendeleev's predictions for the general acceptance of his system, see Brush 1996.

[2] Christensen 1884, p. 311. On the beryllium anomaly, see Van Spronsen 1969, pp. 300-302.

Thomsen and Christensen were not the only Danish chemists who paid tribute to the periodic system in the 1880s. A 23-year old graduate student in chemistry, Rudolph Koefoed published in 1885 an extensive survey article on what he called the periodic law and in which he referred to Mendeleev's as well as Lothar Meyer's works of 1869-71. Like Christensen, he assigned much significance to the successful predictions of gallium and scandium. Ironically, adding to Koefoed's confidence in the periodic system was that it –apparently– resulted in atomic weights in agreement with recent measurements. For example, it was well known that tellurium's atomic weight of 128 conflicted with the periodic system, which required a value about 125. However, as Koefoed was happy to report, recent determinations made by Bohuslav Brauner gave just this value and "thus confirm Mendeleev's prediction."[3]

The system in textbooks and education

While the periodic system seems to have been well known among Danish chemists by the mid 1880s, naturally it took some time until it percolated to the level of education and became part of the teaching of chemistry students. Most university lectures in inorganic chemistry were given by S. M. Jørgensen, who however chose to ignore the periodic system. The system was absent from both the first and the second editions of his textbook on inorganic chemistry, published in 1888 and 1896, respectively.[4] Nor was the system to be found in his 1902 textbook on general chemistry, which was widely used and translated into several languages.[5] In this work Jørgensen listed the chemical elements and their atomic weights alphabetically, without any indication of relations between them. The discoveries of gallium and scandium were duly mentioned, but again without mentioning their relations to Mendeleev's system. This is all the more remarkable in regard of the fact that Jørgensen also disregarded the periodic system in the second edition of 1913. The absence of the periodic system was noted in an otherwise positive review in the German periodical *Naturwissenschaftlicher Rundschau*:

> Neither the periodic system of the elements nor the related question of a primary matter is mentioned in the book. The reviewer is unaware of the author's reason for this reservation, but it seems to him [the reviewer] that this question –which possibly goes deeper into the philosophical foundation of chemistry than any other subject– might well have fitted into the book.[6]

The first university-level textbook to incorporate the periodic system, written by Odin Christensen in connection with his lectures at the university, appeared in 1890 and ran through four editions. Without mentioning Mendeleev by name, he introduced his system in the form of an appendix, not as an organizing principle for treating the properties of the elements.[7] Using "periodic system" interchangeably with "periodic law," his main justification for the classification was its ability to predict new elements in accordance with later experiments.

Another advocate of the periodic system was Emil Petersen, who after studies in Paris and Leipzig had taken up the new physical chemistry of the Ostwald school. In 1889 he gave a lecture series at the University of Copenhagen on the rarer elements, with special emphasis on the problem of their places in the periodic system. By that time he was convinced of the basic truth of the system and also that it reflected an underlying unity of matter.[8] After having been appointed professor of chemistry in 1901, he wrote a textbook in inorganic chemistry in which he included a fairly detailed account of the system. According to Petersen, the periodic system was a useful classification, yet "it is far from a perfect expression of the facts [and] … many deficiencies are attached to it." Among these deficiencies he mentioned the Ar-K and Te-I atomic weight inversions. On the other hand, he was convinced of the importance of the periodic system, not least because "in several cases the existence of elements and their main properties were predicted in advance, many years before they were actually discovered." Rather than mentioning the classic cases of gallium, scandium and germanium, he called attention to the new element radium, "which is very similar to barium and, with an atomic weight of 225, fits nicely into the system."[9]

Among the elementary textbooks intended for the gymnasium schools that appeared in the early part of the twentieth century, some referred to or made use of the periodic system. This was the case with a book written by Julius Petersen, a polytechnically trained chemist who in 1908 was appointed professor of chemistry at the University of Copenhagen. Petersen followed the tradition by emphasizing the successful predictions of elements based on Mendeleev's system, and at the same time he, much like his colleague and namesake Emil Petersen, pointed to its incompleteness and problems such as the Ar-K

and Te-I atomic weight anomalies. Another book for the gymnasium, written by the teacher Hans Rasmussen, is noteworthy because it presented the periodic system in the unconventional form suggested by Julius Thomsen, with vertical groups and horizontal periods.[10] The pedagogical value of the system was not always appreciated, and some teachers suggested that it, being too theoretical, should not be part of the curriculum. It took until 1958 before the periodic system became a formally required part of the Danish gymnasium education system.

Speculations on the complexity of atoms

A pioneer of thermochemistry, Julius Thomsen was first and foremost an experimentalist. Yet he also had an interest in chemical theories, and he was the only Danish scientist who, until Bohr in 1913, actively examined and contributed to the understanding of the periodic system. As mentioned, ever since the 1860s he entertained the heterodox view that the atoms of chemistry are complex particles and that this is revealed by regularities in their atomic weights. In a work of 1887 he connected for the first time this idea with the periodic system, undoubtedly inspired by an address that William Crookes had given the year before to the British Association for the Advancement of Science.[11]

Thomsen was particularly concerned with the question of why only some atomic weights are realized in nature, while other possible weights seem to be missing. An ardent advocate of so-called inorganic Darwinism, he thought that the answer was to be found in the slow evolution of elements from simple to more complex structures. “The right of the fittest has manifested itself and only allowed the formation of atoms with a structure firm enough for a continuous existence,” he wrote.[12] As to Mendeleev’s system, he praised it for its ability to identify missing elements and predict their properties, such as had been the case with gallium, scandium and germanium. Contrary to Mendeleev and most other chemists, he was convinced that the system was a key to understand the complexity of the elements and that it would eventually be possible to represent it as a mathematical function of the atomic weight. Like the Irish chemist Thomas Carnelley had done the year before, Thomsen suggested an analogy between the chemical elements and the hydrocarbon radicals.[13]

The questions addressed by Thomsen were taken up also by Emil Petersen, who in 1890 discussed the nature of the chemical elements and the idea of a basic unity of matter such as discussed by Crookes and others.[14] Evidently in sympathy with the idea, he suggested that it received support from the periodic system. “It is hardly to doubt,” he wrote, “that in this way we will eventually get insight into the unity that lies behind the varied diversity of the elements.” Petersen admitted that the dream of a primary matter was somewhat speculative, but he nonetheless found the dream worthy of pursuit. Whether in Mendeleev’s or Meyer’s version, he thought highly of the periodic law, which he summarized in the formula “The properties of the elements stand in a periodic relationship to the atomic weight.” He explained that there were two major reasons for accepting the truth of the law, the one relating to its unifying power and the other to its predictive power:

> It is the merit of the periodic law that it has arranged all known elements –and in some cases also unknown elements– in one coherent system and demonstrated the intimate mutual relationship between their properties. … These and other applications of the system are of considerable scientific importance. Another application of the system is less important, but on the other hand more striking and amazing, namely, its ability to predict as yet undiscovered elements –to predict their existence and most important properties years before there were actually discovered and manufactured.[15]

That is, according to Petersen the scientific value of the periodic law was primarily its ability to arrange the elements into a coherent system, whereas he gave lower priority to its predictive power. No other Danish chemist expressed a similar view.

To return to Thomsen, in a memoir of 1894 published by the Royal Danish Academy of Sciences, he offered a detailed examination of the atomic weights and their significance. His purpose was to establish that they, if only properly interpreted, revealed that “the so-called atoms of our elements have evolved out of combination of particles of a common basic substance.”[16] He did not on this occasion discuss the relation to the periodic system, but this is what he did the following year, in a paper in which he proposed a new classification of the elements.[17] From a formal point of view,

Thomsen's innovation was merely to reverse periods and groups, which was not entirely original since versions of this kind had been proposed earlier, by Thomas Bayley in 1882 and Carnelley in 1886. However, in 1894 Thomsen was unaware of these two systems, such as he stated in a letter to the American chemist Francis Venable, who in a book of 1896 described Thomsen's system in some detail.[18]

Thomsen designed his version of the periodic system in such a way that it immediately suggested a common origin of the elements, that is, an evolutionary interpretation. Irrespective of such an interpretation, it included several novel features and indicated the existence of possible new elements. For example, it was the first version of the periodic system that included the correct number of rare earth metals, namely 14, and placed this group between cerium and an unknown element of atomic weight 180 with chemical properties analogous to those of zirconium. This hypothetical element –later identified as hafnium– also implicitly appeared in Mendeleev's original periodic system of 1869, but it was only with Thomsen that it was given explicit attention and placed outside the rare earth group.

Another feature of Thomsen's brief paper deserves mention, namely the "curious fact" that the number of elements in the periods are 1, 7, 17 and 31. These numbers, Thomsen pointed out, can be written as 1, 1 + 2×3, 1 + 2×3 + 2×5, and 1 + 2×3 + 2×5 + 2×7. Expressed slightly differently, the number of elements follows the expression $N = 2n^2 - 1$, or, if the inert gases are included, $N = 2n^2$. "Is this relation more than a coincidence," Thomsen asked, cautiously answering that, "Only the future will show, but I have nevertheless wished to expose the possibility of a more profound cause."[19] He probably referred to a systematic arrangement of the proto-atoms of which he assumed the elements to be built up, such as he had indicated in his essay of 1887. The numerical law suggested by Thomsen came to be known as Rydberg's rule, after the Swedish spectroscopist Janne Rydberg who proposed it in different forms in works of 1906 and 1913. Apparently Rydberg was unaware of Thomsen's earlier speculation.

The position of the inert gases

It is well known that the discovery of argon in late 1894, and also of helium half a year later, caused a major problem for the periodic system. The problem was not only that there was no natural place for argon, but also that the new gas appeared to be mono-atomic and with an atomic weight of 39.9, greater than the one of potassium. However, the crisis disappeared and was turned into a triumph when it was realized that the new inert gases could be added as a separate group of zero-valence elements. This was an important test for the still young periodic system, and it has been suggested that the successful incorporation of the inert gases was of no less importance for the authoritative status of the system than the earlier predictions of metallic elements.[20]

The problems that emerged with the discovery of argon were known among Danish chemists and reflected in their works. It were these problems that induced Thomsen to "publish some ideas, with which I have been occupied for years, but which I have wished not to publish until now, because I would not encumber science with unverifiable hypotheses."[21] The ideas he referred to were probably mathematical relations between the electrochemical character of the elements and their atomic weights. From such considerations Thomsen argued that there supposedly existed a new group of chemical elements that were electrochemically indifferent and possessed zero valence. Moreover, based on his new and still unpublished periodic system he suggested that the atomic weights of the elements –of which only argon was known at the time– were 4, 20, 36, 84, 132, and 212. For the seventh period he proposed that it would end with a noble-gas element of atomic weight 292. Like several other scientists at the time, Thomsen searched for a mathematical representation of the periodic system, and he thought that his new extension of the system was a step in the right direction.

In his essay of 1887, Thomsen speculated that the hypothetical solar element, helium, might be a subhydrogenic primary element. When he read his paper on the inert gases to the Royal Danish Academy on 19 April 1895, William Ramsay had not yet announced his discovery of helium in terrestrial sources. Helium initially raised questions with regard to its place in the periodic system, but after a couple of years it was realized that it and argon belonged to a new group, in agreement with Thomsen's proposal. Thomsen kept an interest in the inert gases. In 1898 he gave an address to the 15th Scandinavian Meeting of Natural Scientists, held in Stockholm, in which he emphasized the scientific importance of what appeared to be a new group of gases belonging to the periodic system.[22]

Thomsen was not the only Danish chemist with an interest in the new gases. In a survey article addressed to Scandinavian pharmacists of June 1895, Emil Petersen discussed the sensational discovery made by Ramsay and Lord

Rayleigh.[23] In agreement with the "two distinguished British chemists," he concluded that the evidence spoke in favour of argon being mono-atomic and with an atomic weight close to 40. He was confident that there was no fundamental disagreement between argon and Mendeleev's system. After having discussed various solutions to the problem of argon's place in the system, he ended up with suggesting that the standard version of Mendeleev's system was probably incomplete.

Conclusions

Although dating from 1869, Mendeleev's periodic system was only explicitly noticed by Danish chemists about a decade later. By the mid-1880s it seems to have been broadly known and also accepted as a useful classification by many chemists. The delay in the reception was not unusual, if compared with other small countries, and it does not indicate any particular backwardness of chemistry in Denmark. The system or law was considered of interest only by relatively few chemists, whereas it tended to be ignored by the majority who worked within the more practical fields of chemistry, such as related to engineering, pharmacy and dairy products. Generally speaking, one should be careful not to confuse lack of references in the literature with ignorance: Although the periodic system was not mentioned very frequently by Danish chemists, this does not mean that it was unknown or considered unimportant.

One indication of the status that Mendeleev, and by implication the periodic system, enjoyed in Denmark is that on 5 April 1889 the Russian chemist was elected a foreign member of the Royal Danish Academy of Sciences and Letters. Julius Thomsen served at the time as president of the Academy, and it appears to have been on his initiative that Mendeleev was invited to become a member of the prestigious society. The letter of motivation was written by Thomsen and signed jointly by him and S.M. Jørgensen. Denmark's two leading chemists, both of them of international repute, motivated their proposal as follows:[24]

> Mendeleev's name has become even more generally known by his brilliant work on the theory of how the chemical and physical properties of the elements depend on their atomic weights –the so-called periodic system. In this way he has opened a wide field for a philosophical discussion of the most important chemical phenomena; his theories have several times been remarkably confirmed by the discovery of elements whose existence and most important properties he had predicted as a consequence of the system. Objections can indeed be raised against the full justification of the system, such as can be done against many other theories; but the system has, to a very high degree, advanced chemistry as a science, and for this reason Mendeleev's name will for ever be inscribed among the first in the history of chemistry.

As seen from the perspective of Danish chemists, the periodic system was of importance primarily because of its successful predictions of new elements. It was this feature which provided the system with a measure of credibility and authority. Because the predictions were associated with Mendeleev and his version, rather than the versions of Meyer and others, the periodic system was invariably associated with the name of the Russian chemist. Whereas the periodic system did not appear prominently in Danish academic textbooks in chemistry between 1880 and 1900, it was introduced in elementary textbooks at a relatively early date. By 1910, most Danish students in the gymnasium schools would have encountered the system, if only in its most rudimentary form. On the other hand, both in university and gymnasium level textbooks it typically appeared isolated from the systematic description of the elements and their properties.

Given the vast difference in the amount of consulted sources, whether textbooks or articles, it is problematic to compare the case of Denmark with Stephen Brush's much more detailed study of the reception in the United States and Britain. Nonetheless, I think two comments may be appropriate. First, among Danish chemists the prediction of new elements was generally given more attention than the correlation between the physico-chemical properties and atomic weights. This is contrary to what Brush found in his survey. Second, Brush observes that in chemistry textbooks the periodic system was "not as a rule introduced at the beginning or used as an organizing principle for those books."[25] This conclusion fully agrees with my more limited study of the Danish case.

PICCINI, CIAMICIAN AND THE PERIODIC LAW IN ITALY

Marco CIARDI[1], Marco TADDIA[2]

marco.ciardi@unibo.it
[2]"Giacomo Ciamician" Department of Chemistry, Università di Bologna, ITALY
marco.taddia@unibo.it

Abstract

The paper discusses the reception of the periodic law in late nineteenth-century Italy. The research main objective is to fill a serious gap in the ambit of studies in the history of chemistry in Italy in the period that runs from the mid-nineteenth century to the early twentieth century. Despite the unquestionable level of professionalization and specialisation that the historiography of science and technology has attained also in Italy, the temporal arch that the study intends to consider, still today represents a largely unexplored territory, firstly for the lack of a systematic exploration of primary sources, such as collections of letters, manuscripts and archive documents.

In the period considered, despite a series of delays and shortcomings mainly on the structural and organisational levels, Italy played a leading role thanks to the work of several extraordinary protagonists like Stanislao Cannizzaro, Giacomo Ciamician, and Augusto Piccini. If the relationship between Cannizzaro and Mendeleev are well known enough, we have more to learn about Ciamician and Piccini. For example, a fundamental spectroscopic study of the young Ciamician about spectroscopic analogies between elements in the same group was remembered by Mendeleev in his 1889 Faraday Lecture; at the same time, Piccini studied with originality many aspects of the periodic law, and he was in correspondence with Mendeleev.

The study will especially concentrate on the development of Mendeleev's ideas in Italy under the profile of theoretical development, as well as in relation to the growth and definition of its pedagogical uses by means of a survey of Ciamician and Piccini notes and textbooks.

The first encounter between Mendeleev and Italy occurred in October 1860, after the Karlsruhe Congress. Together with his friend Borodin, who also was a member of the Russian delegation at the Congress, Mendeleev crossed over the St. Gotthard Pass and travelled to Genoa, where he spent the night of 15th October. The following day, they both left for Civitavecchia. Mendeleev liked Italy very much; he wrote: "We enjoyed Italy so much after the suffocating and reserved life spent in Heidelberg". On arriving in Rome, Mendeleev and Borodin visited the Basilica of St. Peter and the Sistine Chapel, where they admired not only the frescoes of Michelangelo, but also attended a solemn mass celebrated by the Pope.

The years passed and Mendeleev became known as a scientist and one of the most important Italian scientific institutions, the Reale Accademia dei Lincei,with its seat in the capital, nominated him a Corresponding Member (1893). To this acknowledgement was added that of the Reale Accademia delle Scienze of Turin (1893) and, some while later, that of Bologna (1901).

After his death in St. Petersburg on the 2nd February 1907, Mendeleev was commemorated at the Lincei by Raffaello Nasini, a physical chemist of considerable prestige. According to Nasini [1], the ideas of Mendeleev started to be taken seriously in Italy around 1878, especially thanks to Cannizzaro, who was in charge of the Istituto Chimico of Rome. As he declared, Mendeleev owed a lot to the so-called pamphlet of Cannizzaro ("Sunto") distributed at the Karlsruhe Congress of 1860. In 1880, the Tuscan Augusto Piccini joined the Cannizzaro group as an assistant. It was probably Cannizzaro that entrusted the study of the periodic system to Piccini and Francesco Mauro. The two chemists undertook experimental researches on certain rare elements but, as we will see, it was Piccini above all who stood out, introducing an integration to the periodic system necessary to support the classification and diffusing in Italy the ideas of Mendeleev in his writings. At the same time as Piccini, Giacomo Ciamician joined the Cannizzaro group and the two became friends so much that on the death of Piccini, it was Ciamician who pronounced the funeral oration.

In this communication, a short biographical profile of both men will be presented and it will be seen why their names have remained connected to the success of the Mendeleev system in Italy.

Nevertheless, precedence must be given to an unfortunate previous attempt of Piccini's work. It was the initiative of Paolo Tassinari (1829-1909), a chemistry professor in Pisa and a brilliant teacher and author of one of the first Italian didactic tests containing the atomic theory. Before the French translation of Mendeleev's work was published, Professor Tassinari, as soon as he heard the news of the discovery of gallium (1875), urged a young Russian born student in his laboratory called Alessio Alessi (Moscow 1857 - Reggio Emilia 1934) to translate it into Italian. Alessi asked Mendeleev's permission to publish it; he agreed, but it was not easy to find the means. He entrusted the publication to a small journal called the *Monitore dei Farmacisti* and after numerous hesitations it was decided to publish a page every now and again, unfortunately with various typographical errors. Discouraged, and once the French translation came out, Alessi interrupted his publication.

Augusto Piccini

He was born in 1854 in San Miniato in the province of Pisa and graduated in chemistry at the University of Padova in 1876 [2]. After several years spent at the School of Cannizzaro, in 1885 he was called to teach general chemistry at the University of Catania. Two years later, he returned to Rome to teach docimastic chemistry at the School of Application for Engineers in Rome. Finally, in 1893 he transferred to Florence where he was called to teach Pharmaceutical and Toxicological Chemistry at the Istituto di Studi Superiori.

Piccini applied himself to organic chemistry and then to chemical analysis, and successively started to cultivate a special commitment to inorganic chemistry. He soon demonstrated a complete familiarity with the system by a dissertation on the oxidisation of titanic acid published in 1882 in the Records of the Reale Accademia dei Lincei [3], that was followed by a similar article in the *Gazzetta Chimica Italiana* in 1883. To understand the work of Mendeleev, Piccini started to study Russian in 1883. From that moment, as Giulio Provenzal described, who was a student of Piccini from 1892 to 1895, Piccini became "the best exhibitor and at the same time the best critic of the periodic system". Above all, he succeeded in integrating his translation of the "Treaty of Inorganic Chemistry" by Victor von Richter with a long appendix (55 pages; 30 of which were dedicated to the system) which was published in 1885 [4]. Piccini particularly dwelled upon the controversies of limit forms and *extra limits* of the elements and particularly asking if peroxides (BaO_2 and others) should also be taken into consideration, because in that case it would be necessary to shift the maximum limit. After a general review of the groups, he concluded by suggesting a closer study of the dependence of properties to combination form; a dependence that creates "in one same element a quantity of partial relations with many others that are different". His objective was to construct a "large picture in which the truths discovered by Mendeleev would be harmonised with those that in his time would be discovered". Giulio Provenzal lived the emotion of that moment with the master of the discovery of the first noble gases: "a new and huge problem with regards to the periodic system". The discovery did not affect Piccini's faith in the Mendeleev system. In 1903, Piccini published in the first volume of the "New Chemical Encyclopaedia" [5], run by the chemist Icilio Guareschi, one of the most important historical articles of Italian chemistry; a long article that would have represented not only his scientific testament, but also an extraordinary work of popular science of Mendeleev's work. The Tuscan chemist explained: "For more than thirty years the periodic law has received secure confirmations and questionable confutations. No fact, definitively verified, is discovered to invalidate the spirit and the letter". Naturally, everything was meant as "healthy criticism", without demanding more from the periodic law than it could promise. The same Mendeleev, wrote that Piccini, "also recognising that the analogy concept of the elements, summarised in the identity of the combination limit, is that which is destined to remain in science", was aware that "the theoretical foundation of the periodic law" was missing. In short, the periodic law was like the "laws of Kepler waiting for Newton to explain it".

The presentation of Mendeleev's work was carried out by Piccini, above all in the fifth chapter of *Numerical relationship between atomic weights and the elements.* In this chapter, the Tuscan chemist retraced the history that brought to the "idea of establishing the true function that connects all atomic weights with the physical and chemical behaviour of all elements". Piccini supported the view that precursors to Mendeleev's work did not exist. The work of the Russian chemist was an absolutely original creation. After dwelling on the theory of William Prout, Piccini dedicated ample space to the exposure of Mendeleev's dissertations of 1869 and 1871 that were compared to the dissertations of Lothar Meyer. At the end of the examination, Piccini's judgement was unequivocal: "Meyer did not discover the periodic law, either independently or dependently of Mendeleev". According to Piccini, Mendeleev's work was comparable to that of Lavoisier, also an author of a revolution, because he knew how to "interrogate facts known for a long time and facts just discovered, forcing them to reveal their jealously guarded secrets".

The exposure of the real periodic system followed the historical part, with the presentation of the most recent Mendeleev's table. In the final part of the article, Piccini also dealt with the difficult question of "objections to the periodic law". In particular, he again dwelled upon the problem of the choice of "combination limit", summarising his contribution to the discussion and investigations on peroxides, claiming them to be a priority.

Mendeleev gave credit to Piccini for the diffusion of the periodic system. In a letter sent to Piccini on the 29th January 1903, Mendeleev wrote: "I am really pleased to see a scientist in a far-away country that is so profoundly well-versed in the principles of the Periodic System".

Giacomo Ciamician

Giacomo Ciamician (Trieste 1857 - Bologna 1922) was the first Italian chemist presented as a candidate for the Nobel Prize. On the occasion of 150th anniversary of his birth, Bologna hosted a scientific meeting and one of us (M.T.) reported new biographical studies useful for understanding his scientific career [6]. Ciamician's name could be placed in relation to Mendeleev's periodic system for:

1. The early researches on spectroscopy conducted in Vienna.
2. His activity as Chemistry Professor at Bologna.

Ciamician studied in Trieste and Vienna and graduated in Giessen in 1880. During the Viennese period, Ciamician the student committed himself to cultivating various scientific interests, frequenting certain laboratories of the Polytechnic. The precociousness of the genius is deducted by approximately fifteen communications, partly published between 1875 and 1879. Of particular interest were the researches on spectroscopy that ended in the physics laboratory run by Professor Pierre, when Ciamician was not even twenty years old. The results were published in the *Wiener Sitzungsberichte* signed by "G. Ciamician, *Chemical Student*". The work that was of major interest was "Spectra of chemical elements and their compounds" that was followed by the effect of pressure and temperature on emission spectra. With the first work, Ciamician highlighted the spectral analogies between elements of the same group of the periodic system, achieving the analogy that was defined as the *law of homology* and overtaking the previous researches of Huggins and Thalén relative to emission spectra of metals, as well as that of Salet on non-metals. In 1880, he extended his research of analogies to 20 elements and to a certain number of compounds. He published the new works in the *Monatshefte für chemie* and also illustrated the equipment utilised. Ciamician found that the spectral lines of chemically similar elements (e.g., O, S, Se, Te) were comparable singly or in groups. He concluded that a natural group of elements had its characteristic spectrum, that differed from the single members of the same group, except for the fact that the homologous lines (*lines that fluctuate in the same measure from discharge to discharge*) shifted towards one side or the other side of the spectrum. This meant that the wavelengths of the transitions increased or decreased and that, amongst other things, certain lines or groups of lines disappeared. In the second work: "The influence of density and temperature on vapour and gas spectra", he analysed the spectral behaviour of chlorine, bromine and iodine, as well as the vapours of mercury and sodium. He noticed that the spectra of elements appertaining to groups of halogens changed notably, depending on the temperature and pressure conditions, with regards to the number of spectral lines and the intensity of the same. For this reason, different spectra (partial spectra) can be distinguished for each of the elements, corresponding to different pressure intervals from which a complete spectrum of the element can be reconstructed. Taking into examination the variable lines caused by pressure, he formulated the relation between the various partial spectra of different elements. For example, he saw that the spectrum of diluted bromine vapours came closer to the spectrum of chlorine the more he diluted the vapours, whilst the spectrum of concentrated bromine vapours seemed more comparable to the spectrum of iodine. If all the lines that appear distributed in the various partial spectra for each element of the halogen group are grouped together and make a complete spectrum, he noted that the three complete spectra were perfectly similar, with a decrease in the wavelength of the homologous line passing from chlorine to iodine. Mendeleev acknowledged the contribution of Ciamician on the confirmation of the periodic system in the "Principles of Chemistry". In the 1891 German version, two citations of Ciamician's work are found.

Also in the article "The Periodic Law of the Chemical Elements" by Dmitrii Mendeleev, published in 1889 by the *Journal of the Chemical Society* and taken from the Faraday Lecture, Mendeleev recognised the contribution of Ciamician. N.B. "A distinct periodicity can also be discovered in the spectra of the elements. Thus the researches of Hartley, Ciamician, and others have disclosed, first, the homology of the spectra of analogous elements; secondly, that the alkaline metals have simpler spectra than the metals of the following groups; and thirdly, that there is a certain likeness between the complicated spectra of manganese and iron on the one hand, and the no less complicated spectra of chlorine and bromine on the other hand, and their likeness corresponds to the degree of analogy between those elements which are indicated by the periodic law" [7].

After the degree at Giessen, Ciamician joined the group of Stanislao Cannizzaro in Rome, where he continued with brilliant researches on pyrrole started in Vienna (Ciamician-Dennstedt reaction, 1881), and started to study photochemistry. He became extraordinary professor in Padua in 1887 and after only two years, was called to hold the chair of General Chemistry at Bologna. At Bologna, Ciamician carried out important researches in the field of photochemistry and the chemistry of natural substances and plants. Ciamician took great care in teaching and his lessons earned the applause not only of the students but also of citizens who came to listen as unregistered students. Ciamician never collected his lessons into books or in lecture notes. The lessons of his last academic year in which he taught (1920-1921) were reconstructed by Bruno Ghetti. Previously, notes of his lessons were collected by students Bruno Maggesi and Andrea Stagni and were repeatedly checked until approximately 1915. In these notes, the periodic system occupied less than eleven pages. It was preceded by three pages dedicated to the "Theory of Valency" that were followed by nine pages of "Systematics". Ciamician started his presentation defining the periodic system of elements: "in the field of chemistry, one of the most successful attempts of expressing the qualifying differences via numerical data between the various objects of the study". After dabbling with the theory of triads, Newland's law of octaves and the studies of Lothar Meyer, Ciamician passed immediately to Mendeleev and he remembered the guiding concept: "a connection exists that algebraically we still ignore, between the atomic weight of an element and its property". He recounted that Mendeleev, distributing the elements according to the order of increasing atomic weights (H being a unit of measure), had observed an evident regularity corresponding to the distribution in periods, and a repetition with the same characters of the physical properties and the chemical behaviour. This regularity appeared to stop after potassium because seventeen termini were required, and not seven, to arrive at the halogen bromine. In this series, two sub-periods of seven termini each could be seen, joined together by three new "transitory" termini between Mn (negative) and Cr (positive). The same situation repeated itself approximately between bromine and iodine. The periods of seven termini were defined as "small periods" and the others as "large periods", with each period subdivided into sub-periods of seven termini. Taking the elements on the same horizontal line, groups of "bodies" having similar physical and chemical properties were constituted. Ciamician noted that certain periods were incomplete and he dwelled upon the unknown element with an approximate weight of 100. This element had disappeared or had not yet been discovered. We now know that this element is technetium, the discovery of which occurred in December 1936 by Perrier and Segrè. Mendeleev left numerous other places vacant that were occupied much later. After certain considerations on the periodic function, that was not continuous but "in leaps" and therefore not representative of a geometric function but a numerical function, Ciamician affirmed that the periodicity was a complex function that was not completely clear. Certain considerations followed on the general properties of the groups and the observation was made that from the position of one its valency could be deducted immediately and therefore the form of combination limit. A table was presented in which elements were put in order depending on the limit valency and their limit oxide which highlighted the more or less accentuated acid or basic character. Passing to dealing with compounds different from oxides (e.g., hydrogenates and chlorinates) after having lingered over "special forms", Ciamician acknowledged the difficulty in correlating the periodic system with Dalton's law. The position of an element in the periodic system does not therefore depend only on the atomic weight but also on the physical and chemical properties. Mendeleev thought about the existence of other elements, the properties of which he was able to foresee. After the discovery of gallium (1875), scandium (1879) and germanium (1886), the system of the Russian chemist was "universally accepted". Ciamician affirmed that the systematic order of Mendeleev was "up until now the best attempt" and asked if it was possible to discover new elements. He was certain of it and returned to the atomic weight 100 and advanced the hypothesis that periods could be completed. Maybe one day, "periodicity could become greater and the elements of the system will be subject to a different arrangement". After a retest regarding the recent discovery of new elements (noble gases), of which the compounds were not known, their properties were thought to be monatomic. They did not come within the periodic system because this was based upon the combination form. The new group should be called group 0. Ciamician also spoke about recently discovered rare earths, to be positioned between lanthanum and ytterbium. He then lingered over the particular behaviour of oxygen, which was anomalous in terms of valency. The main inconsistencies of the system left were two:

1. Nickel, that followed cobalt because of its chemical properties, had a lesser atomic weight (Co=59, Ni=58.7)
2. Iodine, that followed tellurium, was always thought to have a lesser atomic weight (126.97 against 127.9). Ciamician said that maybe it was an experimental error.

A law so general created many problems that, according to Ciamician, from the field of experience were transported into a "fantasy" world. For him, phenomena of radioactive bodies reinforced the hypothesis that a single fundamental material existed from which the various elements were derived from, whilst "from experiences and reasoning of electrochemical nature, he was mislead into believing that electrical material was constituted of electrons". Ciamician gave space to the interpretation of those who thought that the order of the elements in the Mendeleev classification did not depend on the weight but the electrical charge of the atoms. Referring to the hypothesis of Rutherford, Van den Broek and Bohr on atomic structure, he affirmed that they found confirmation in the spectra of emissions of elements in the x-ray zone obtained by Moseley.

Presenting the final table, organised according to the atomic numbers, or rather "the algebraic sum of the quantities of positive and negative electricity existing in the nucleus of an atom", Ciamician explained that for each group of isotopes, only one was indicated and that only six elements before uranium were left to be discovered. Considering that the experiment of Geiger, Marsden and Rutherford was carried out in 1911, as well as Van den Broek's article in *Nature*, whilst the Bohr model, like the experiments of Moseley were carried out in 1913, it can be said that Ciamician took care of the updating of the lessons almost in real time.

On 7th November 1903, Giacomo Ciamician held the solemn inauguration of the 1903-1904 academic year of the University of Bologna. His dissertation was entitled "Chemical problems of the new century" [8]. Quoting Mendeleev's system, he said that "As our Piccini demonstrated by words and facts, it was the only guide of the intricate labyrinth of inorganic chemistry for thirty years and numerous researches based upon it inspired a great quantity of results». Certainly, the system was passing through some difficulty. Notwithstanding that, according to Ciamician it should be "transformed", "but not swept away on a wave of scientific progress". He was right.

Abstract

A. v. Antropoff combined the ideas on the periodic system of chemical elements of previous authors into an impressive and colorful-mnemonic graphical design, to act as an ordering principle in both research and education. He stressed the development of elements along the linear array of nuclear charges from Z = 0 to 92, the pseudo-periodicity of 2, 8, 18 and 32, and the kinships of main groups and subgroups. His design was largely lost in Germany after WW II, partly due to his Nazi affiliation. However, his scientific legacy was transferred to Spain. In 1928 Antonio García-Banús, professor of Organic Chemistry at the University of Barcelona, made a study trip to Europe including Germany. At his return he proposed the creation of a lecture hall with references to chemistry, with a wall painting of the periodic table of v. Antropoff. This took place in 1934. After the Spanish Civil War, the painting remained in the classroom, and was restored in 2008. We have yet not heard of any other still existing wall copies of this design.

Introduction

We review the history of the ideas behind the periodic system of chemical elements and its various graphical representations (sect. *Discovery of the Principles of the Periodic System of Chemical Elements*, see van Spronsen 1969; Mazurs 1974; Scerri 2007; Leach 2010). In 1926 von Antropoff, professor of Physical Chemistry of the University of Bonn (Germany), combined some of those ideas with colors in a very satisfying and impressive balance (sect. *Von Antropoff's Eclectic Periodic Table of 1926*). A short biography of von Antropoff is given inbetween (sect. *Andreas von Antropoff*) Von Antropoff's periodic table became quite popular in German schools, but quickly disappeared after World War II. However, von Antropoff's visiting professor García Banús reproduced it at the wall of the lecture hall at the main building of the University of Barcelona (Spain). It is still there and it has been restored in 2008 (sect. *Propagation of von Antropoff's Design from Germany to Spain*).

History and Significance of von Antropoff's Graphical Representation

1. Discovery of the Principles of the Periodic System of Chemical Elements

After Boyle (1661) had suggested an experimentally based modern-science definition of chemical elements, Lavoisier and his companions (Guyton de Morveau et al. 1787; Lavoisier 1789; Fourcroy 1800) eventually identified the first few dozens of them. Soon, endeavors were initiated to arrange these elements in a systematic order, thereby displaying the similarities and the various trends of chemical and physical properties of their compounds. Gmelin (1817, 1843, 1852) for instance created two-dimensional arrangements of most similar elements (halogens, chalcogens, pnicogens, etc.; alkali metals, alkaline earth metals, earth metals, etc.) along one direction, and a systematic variation of properties of these element groups (such as valency, electrochemical behavior etc.) in the other direction.

Relations between the atomic or the equivalence weights of the elements were already discovered by Döbereiner (1817) and then more relations were found by several scientists in subsequent decades, nicely described by van Spronsen (1969). But the great breakthrough came only after Cannizzaro's (1858) clarification of the two different weight concepts and of the valence numbers at the first international congress of chemistry in Karlsruhe (Anonym 1860). Now the chemical elements could be arranged on a (nearly) unique *linear array*, as done for the first time by Béguyer de Chancourtois (1862). In order to display the various relations and so-called periodicities of the properties, numerous layouts were suggested for the graphical representations of the system of elements (Mazurs 1974; Leach 2010). The periodicity was pin-pointed by the repeated occurrence of two very different elements directly adjacent on the array, namely the halogens and the alkali metals, with the chemically unique noble gases, discovered at the end of the 19th century, now in between (Schwarz and Rich 2010).

Winding the array of elements up on a cylinder, Béguyer (1862) developed a three-dimensional helical design that emphasizes the *continuity of the elemental array* and the relations between *the main groups and the transition groups* (and the inner transition or f elements, found later). Baumhauer (1870) quasi point-projected the helix onto a two-dimensional plane, obtaining a flat *spiral*. Cutting the cylinder before the alkali and coinage metals (i.e. along the yet unknown noble gases) leads to the early short form of rectangular periodic *tables*, where the explicit reference to the continuing array is no longer emphasized (Meyer 1864, 1872, 1870; Newlands 1865; Mendeleev 1869, 1870; and others, see Mazurs 1974).

The increasing lengths of the periods (2, 8, 8, 18, 18, 32, …) and the differences between the main and transition (and inner-transition) groups are better represented, if the array of elements is wound up as a *helix with increasing radius*, or on a cone, or on a cylinder with bulges (Emerson 1911; Stintzing 1916; Courtines 1925). Projection onto a plane yields a spiral with increasing radii (Emerson 1911; Hackh 1914; Clark 1921) or spirals with nooses (Janet 1928). Cutting the helix or cone along the noble gases leads to the early medium or long forms of rectangular tables (Mendeleev 1869; Meyer 1872; Bassett 1892). In order not to fully loose the relation between the main and the subgroups of same index (groups *g* and 1*g*, in modern nomenclature), additional *connecting lines* were inserted (Bayley 1882; Thomsen 1895; Carnelley 1886; Bohr 1922).

Most early chemists accounted for the growing length of the periods in the following systematic manner: the periods of 8 with the p-blocks *after group 1* (i.e. below H and He), the periods of 18 with the d-blocks *after group 2* (i.e.below Be,Mg and B,Al), and the periods of 32 with the f-blocks *after group 3* (i.e. below Sc,Y and Ti,Zr). Akhumov (1946) has nicely displayed it and indicated the hypothetical periods of 50 with g-blocks *after group 4* (i.e.below Ce,Th and Pr,Pa). This corresponds to the observed chemical trends as well as to a realistic order of orbital energies of atoms in molecules (Wang and Schwarz 2009, Schwarz and Wang 2010). Remarkably, the writings of physicists like Bohr (1922) and Madelung (1936) influenced the community of chemists to begin with a new angular momentum shell always after the 2nd column. This nonrealistic "*n+l,n* rule" of orbital occupation, namely $ns < (n\text{-}3)g < (n\text{-}2)f < (n\text{-}1)d < np$ became a 'scientific fact in the chemical community' in the sense of Ludwik Fleck (1935), as discussed by Wang and Schwarz (2009) or Schwarz and Rich (2010).

2. Andreas von Antropoff

Andreas von Antropoff was born on August 16, 1878, in a distinguished German-Baltic noble family in the Estonian capital Reval (now Tallinn) which then belonged to the Russian empire. Since 1897 he studied at the German-Lithuanian Polytechnic of Riga which had become russified. In 1904 he moved to Heidelberg in southwestern Germany, where he worked under the guidance of Professor G. Bredig (one of the founders of the science of catalysis) for his doctoral thesis on the pulsating mercury-H_2O_2 catalysis and on the formation of HgO_2 (Bredig and v.Antropoff 1906; v.Antropoff 1908). During his postdoctoral fellowship in London with Sir William Ramsey, he investigated the solubility of noble gases in water (v.Antropoff 1910). He then obtained the position of an Assistant and later of a Docent at the Polytechnic of Riga, where he continued those researches (v.Antropoff 1919).

During World War I, he acted as a departmental chief at the Central Bureau of Standards in the Russian capital, then called Petrograd. Since he got involved with the liberation of the Baltic region and against Bolshevism (v.Antropoff 1935) and favored the German side, he run into troubles. Eventually, he emigrated to southwestern Germany, obtained the position of an Assistant at the Karlsruhe Institute of Technology, and the German citizenship in 1921. He achieved his habilitation, and in 1925 was appointed as Professor of the new division of Physical Chemistry at the University of Bonn. There he cooperated with the chemical industry, supported Germany's economic autarky (v.Antropoff 1941) and also entered a national-conservative political party.

He published various editions of his introductory study-book of experimental chemistry in German and in Spanish (v.Antropoff 1919, 1955; v.Antropoff 1945). He joined the group of authors preparing the 8th edition of Gmelin's handbook of inorganic chemistry and contributed to the Strontium and Barium volumes (Gmelin 1931, 1932). In 1929 he published, in cooperation with his Assistant von Stackelberg the Atlas of Physical and Inorganic Chemistry (v.Antropoff, v.Stackelberg 1929, 1932), a rich volume of numerical data tables in the format of his Periodic Table (v.Antropoff 1926b, Fig.1). Besides these compilation and review works, he conducted various thermodynamic and kinetic research works, for instance on alkali and alkaline earth carbides, nitrides, halides etc. (e.g. v.Antropoff 1926a, 1932, 1933b) or on gas adsorption at wide ranges of pressure (a long series of papers by v.Antropoff from 1936 till 1955). It is a pity that his early speculation and proof of the existence of noble gas halides (e.g. v.Antropoff 1924a, 1933a) seem to have been nearly forgotten.

After the takeover of power in Germany by the National Socialists, von Antropoff became a member of Hitler's NSDAP party and of the paramilitary SS organization. He organized the raising of the NAZI swastika flag by radical students over Bonn University in 1933 (see Fig. 3 below). Despite his explicit anti-Jewish attitude, he nevertheless supported Einstein's scientific theory of relativity, which was uncommon among the NAZIs. Because of his disputable NAZI activities, combined with medium scientific activities, he lost his professorship after World War II around the date of retirement, and then founded a small pharmaceutical and cosmetic enterprise. He died on June 02, 1956, in Bonn, at the age of 77. (Bonn 2010; Wamhoff and Peter 2010; Leach 2010; Garleff 2008; Harten et al. 2006)

3. Von Antropoff's Eclectic Periodic Table of 1926

Von Antropoff obviously had broad chemical background knowledge. So it is not astonishing that he designed and promoted a periodic table that combined several important aspects of the previous designs in the literature. Von Antropoff recognized periodic tables as most fruitful, organizing principles for research and education in the proliferating field of chemistry. While nature gives us one system of chemical elements, the numerous relations between the elements can be represented more or less efficiently by various graphical designs. The main points he wanted to embody were the *continuity of the elemental array*, the *growing lengths of the periods*, and the more or less pronounced periodicities of the *main, transition and inner transition groups*. In order to obtain some optimal compromise between the short and medium rectangular and pyramidal forms and to account for the kinships between the main and transition groups (Bayley 1882; Thomsen 1895), he suggested the eclectic black-and-white design of Fig. 1 (v. Antropoff 1926b). In that set of two papers, he also suggested a mnemonic coloring of the main groups and their related subgroups (Fig. 2). His tables are distinguished by two characteristics. i) The noble gas at the right end of each row is repeated at the left onset of the next row, thereby highlighting the continuity of the array of elements. ii) Each of the 8 main groups of the upper periods bifurcates into two groups of the lower periods. This was no new idea, but he also indicated the extent of the kinships, for instance between O,S and Se,Te,Po, while Cr.Mo,W,U are less akin (see the yellow region in Fig. 2). On the other hand, Be,Mg are nearly as similar to Ca,Sr,Ba,Ra as to Zn,Cd,Hg and are both uninterruptedly connected by the violet region.

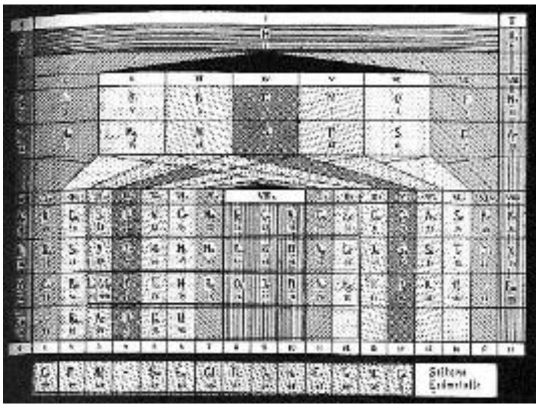

Fig. 1: Von Antropoff's black-and-white Periodic Table (1926b).

Fig. 2: Von Antropoff's colored Periodic Table, as restored in Barcelona in 2008.

The impressive chemical laboratory building of the University of Bonn had been designed by A. W. von Hoffmann in the 1860s when he was to move from London to Bonn, but eventually moved to Berlin. So, the laboratory was finished by, and became the domain of Kekulé von Stradonitz. Von Antropoff managed to get his colorful design of the periodic table onto the wall of the large chemistry lecture hall, often called the Kekulé auditorium. His table became quite common in German chemistry textbooks, but disappeared after the end of the NAZI era. Also von Antropoff's wall chart disappeared during the renovation of the university lecture hall years after the war. On the other hand, Pauling (1949) 'borrowed' von Antropoff's design for his famous book.

Von Antropoff's tables contained seven element symbols of the time that are no longer in use nowadays. For argon, both Ar and A were used, and for xenon X instead of Xe. Thulium was abbreviated by Tu instead of Tm, and iodine by the German J (Jod) instead of I. The old name emanation, Em, was still used for radon. In Germany, technetium and lutetium were at that time called masurium, Ma, and cassiopeium, Cp. The elements francium, astatine and promethium were only found in 1939, 1940 and 1945, respectively, and were still indicated by hyphens. The same was done for the entry Z=0, the neutron. Von Antropoff (1924b) had suggested the element-name neutronium for it. Also, a few other authors included Z=0 or 'n' on their tables, mostly for esthetic reasons, before and after von Antropoff, for instance Emerson (1911), Akhumov (1946) or Longman (1951).

A particular aspect of von Antropoff's table is the appearance of the noble gases at the end of one period and again at the beginning of the next one. He (1926b) stressed the periodic character of the system as a 'cylinder cut along the column of noble gases', so that the latter become the left and right 'corner-pillars' of his PT (see also Wang and Schwarz 2009). He suggested to display (as bars, circles or values) the properties of the elements, such as atomic radii, various thermodynamic, mechanic and electric parameters of the element's compounds on this tabular construction, finally published in his Atlas of 1929. This has nowadays become standard, using the medium long rectangular form advocated for by the IUPAC (2010), see e.g. Lof (1987).

Propagation of von Antropoff's Design from Germany to Spain

1. Antonio García-Banús

Until 1969, the Section of Chemistry of the Faculty of Sciences of the University of Barcelona (UB) was located in the historic building at the University Square of Barcelona, where all theoretical and practical chemistry classes were taught. Antonio García-Banús (Fig. 4), born in 1888, was a renowned professor and researcher in Organic Chemistry since 1915 (Nieto-Galan 2004). In 1928 the university granted him a stipend of 6,000 pesetas to go on a study trip and scientific stay in Germany, France and Switzerland, probably during the period from July to December 1928. During this stay he must have seen various mural periodic tables at the visited schools. The formats of periodic tables so far released in Spain were the Mendeleev models in its various forms, as in the textbooks of Luanco (1898) and Mascareñas (1921).

In 1933 García-Banús was appointed to the Board of the UB, which had received the name *Autonomous University of Barcelona* in accordance with the Statute of Autonomy passed in June 1933. From his position, and among many other tasks, García-Banús promoted several works of conditioning and improvement of the faculties. On 24 September 1933, the Board approved the "Construction of an Auditorium for General Chemistry" (Actas 1933) on the ground floor of the cloister of Humanities. The furniture was changed at the chosen site, and a periodic table was painted on the wall. García-Banús was very proud of that performance, as evidenced by his speech at a meeting of the Faculty Board in December 1934, with the statute of autonomy of the university suspended and some dismissed members of the board in prison (Actas 1933-1946). Because of alleged Republican militancy, García-Banús had to go into exile in 1938. He got a position at the National University of Colombia and then moved to Caracas (Venezuela), where he created a school of organic chemistry. There he died in 1955.

Fig. 3: Andreas von Antropoff in front of the University of Bonn 1933.

Fig. 4: Antonio García-Banús.

2. The Mural Periodic Table of the University of Barcelona

The Barcelona classroom became known popularly as the 'García-Banús room' already before the Spanish Civil War, but obviously this name never became official. All Barcelona students of chemistry between 1934 and 1969 have received some lessons in this room at some point of their studies. Unfortunately it was not possible to find information about the designer or the professional painter of the mural Periodic Table. It is known that on 31 May 1934, the Faculty paid a bill for 3,248 pesetas to Fernando Blasi, and therein was only a note for "Auditorium General Chemistry" without any further specification (Libro Mayor 1934).

The mural is an oil painting, 2.720 × 2.175 m, painted directly on the wall ready and unframed. In 2008 its state was readable but very rough and eroded in many places. The restoration was led by Maria Antonia Heredero, professor at the Restoration Unit of the Department of Painting at the Faculty of Fine Arts of the UB. The work team had been in charge of Sara López Busquets, Marta Sánchez Natera and Mar Rodríguez García. They have followed the current criteria for restoration, using little invasive and reversible procedures when possible. The task of restoration began with a careful examination of the mural, painting solubility tests, sampling for pigment analysis and process photography. The paint layer has been set with Japan paper and Tylose (3% polycarboxymethylcellulose sodium in distilled water). A careful process of cleaning with a concentrated solution of anionic detergent has been carried out in advance. Subsequently the wall has been retouched with Maimieri watercolor paints. Finally the wall has been covered with a protective layer of Paraloid B-72 (trade name of an acrylic resin, a copolymer of methyl acrylate and ethyl methacrylate). The work had been carried out between September and November 2008. We detected the interesting detail that element-entry hydrogen was originally painted in a different color and was later covered by the current navy blue. Also, there are several places with small incisions from 1934 on the plaster wall specifying the names of the colors that had to be painted at each division. These colors resemble the ones in von Antropoff and von Stackelberg's Atlas of 1929, which is still available at several places.

The periodic table in the classroom "Aula García-Banús" is probably the last visible vestige of the residence of the Section of Chemistry of the Faculty of Sciences at the historical University building, that was left in 1969. It is the only existing mural of this design we have heard of. A commercial large periodic table made of fabric and stamped rubber, in not very good state, is kept at the middle school IES Maragall in Barcelona. It has exactly the same design as the painted mural. It has a copyright of 1925 from Verlag Koehler & Volckman AG&Co, Leipzig. At the library of the school they have a copy of the Atlas already mentioned. No information is available on how or when this material was acquired, but it suggests that the materials designed by von Antropoff were quite widespread among teachers at such levels in those times.

Acknowledgments:

The company BASF Española S.L. has sponsored the restoration of the wall table. Vice President and Chief Executive Officer Karl-Peter Bercio initially, and after his retirement Gerhard W. Schwarz, have supported the project, which has been managed by the company's Public Relations and Communications department, headed by Josep Bach and later by Ulia de Domenech. The authors appreciate the support of Ainhoa Carcadilla, Laia Encinas, Marta Fernandez, Neus Jaumot and Isabel Jimenez, of the Historical Archive of the University of Barcelona (AHUB). The comments of Maria Pilar Ricol and Esperanza Colombo have been useful to guide the searches.

CIRCULATION OF MATHEMATICAL KNOWLEDGE IN 18TH-CENTURY BRITAIN: NEW PERSPECTIVES

ROCA-ROSELL, A. (ed.).(2012) *The Circulation of Science and Technology: Proceedings of the 4th International Conference of the ESHS, Barcelona, 18-20 November 2010.* Barcelona: SCHCT-IEC, p. 544.

FRANCIS BLAKE AND THE METHOD OF FLUXIONS

Mònica BLANCO
Departament de Matemàtica Aplicada III, Grup de Recerca d'Història de la Ciència i de la Tècnica, Universitat Politècnica de Catalunya, Barcelona, SPAIN
monica.blanco@upc.edu

Abstract

In 1750 Thomas Simpson published the Doctrine and Application of Fluxions*, which the author considered to be a new book rather than a second edition of his* New Treatise of Fluxions *(1737). It is true that both works contained the direct and the inverse method of fluxions. However, in the preface of the* Doctrine and Application of Fluxions *Simpson stated that this second work was more comprehensive and the principal matters were handled in a different way. In this regard, the relationship between Thomas Simpson and Francis Blake seems to have been crucial in the different approach that Simpson adopted in his work of 1750. Although his usual place of residence was Herrington (near Durham), Francis Blake spent some time in London. There he became a friend and a pupil of Simpson, who had set himself up as a teacher of mathematics in Spitalfields around 1736. Between 1738 and 1740 Simpson and Blake exchanged letters on the subject of the method of fluxions. An immediate outcome of their correspondence was an anonymous tract,* An Explanation of Fluxions in a short Essay on the Theory*, published in 1741 and written by Blake himself. Actually, Simpson mentioned Blake's short treatise in his preface of 1750 and acknowledged his indebtedness to it. Focusing on the direct method of fluxions, the goal of this contribution is to analyse the impact of the communication between Blake and Simpson on the writing of the* Doctrine and Application of Fluxions*. Beyond this particular episode, this analysis provides new insights into the communication of mathematical ideas as developed in Spitalfields at the time.*

In 1750 Thomas Simpson (1710-1781) published the *Doctrine and Application of Fluxions*, which the author considered to be a new book rather than a second edition of his *New Treatise of Fluxions*(1737). It is true that both works contained the direct and the inverse method of fluxions. However, in the preface of the *Doctrine and Application of Fluxions* Simpson stated that this second work was more comprehensive and the principal topics were dealt with in a different way. In his preface of 1750 Simpson acknowledged his indebtedness to a certain short treatise:

> I cannot put an end to this preface without acknowledging my obligations to a small tract, intitled, *An Explanation of Fluxions in a short essay on the theory*; printed for W. Innys: wrote by a worthy friend of mine (who was too modest to put his name to that, his first attempt) whose manner of

> determining the fluxion of a rectangle, and illustrating the higher orders of fluxions I have, in particular, follow'd, with little or no variation.[1]

The anonymous treatise mentioned above had been written by Francis Blake (1707/8-80), a personal acquaintance of Thomas Simpson.What little facts are known of Blake's life are mainly based on his correspondence with Simpson.[2] Educated at Lincoln College Oxford (1725), he became a baronet in 1774. His interests covered experimental philosophy and mechanics, in particular compressibility of water and design of steam engines. He actually contributed with several papers on these topics to the *Philosophical Transactions*, being elected Fellow of the Royal Society in 1746.[3]

Although his usual residence was at Herrington (near Durham), Francis Blake spent some time in London. There he became a friend and a pupil of Simpson, who had set himself up as a teacher of mathematics in Spitalfields around 1736. Between 1738 and 1740 Simpson and Blake exchanged letters on the subject of the method of fluxions. From their correspondence it is clear that Blake attended Simpson's classes in Lincoln's Inn Square (London).

An immediate outcome of their correspondence was an anonymous tract, *An Explanation of Fluxions in a short Essay on the Theory*, published in 1741 and written by Blake himself. Though not significantly popular, Blake's tract was highly regarded for its rigour in rendering the principles of the fluxional method. Besides its reprints of 1763 and 1809, Blake's tract was reprinted as late as 1809 with the fourth edition of John Rowe's *An Introduction to the Doctrine of Fluxions* (1751).[4] It was William Davis[5] who revised and corrected this fourth edition and who added Blake's essay, as the Advertisement reads:

> … he [Davis] has to this fourth edition added that short but valuable little essay on the Explanation of the Theory of Fluxions, printed for Wm. Innys, and taken notice of by the late celebrated mathematician Thomas Simpson, in the preface to his excellent Treatise of Fluxions.[6]

The relationship between Simpson and Blake turned out to be crucial in the approach adopted by Simpson in 1750. It is worth stressing that the definitions, propositions, illustrations and rules included in Blake's essay were literally derived from the correspondence between Blake and Simpson, and subsequently appeared in Simpson's work of 1750. What is more, Blake sent Simpson the introduction and conclusions he intended to include in his essay to have them corrected and discussed. Changes detected in Simpson's work of 1750 regarding the general definition of fluxion, higher-order fluxions and the rule of the product appeared in Blake's essay, as Simpson himself acknowledged in his preface:

> … whose manner [Blake's] of determining the fluxion of a rectangle, and illustrating the higher orders of fluxions I have, in particular, follow'd, with little or no variation.[7]

Compare, for instance, Figure 1, a), b) and c), regarding the rule of the product.

* * *

This contribution is essentially a part of a work-in-progress paper. Focusing on the direct method of fluxions, one of the goals of this uncompleted paper is to analyse in depth the impact of the communication of mathematical ideas between Blake and Simpson on the writing of Simpson's work on fluxions. This, on the one hand, will provide new insights into the role of correspondence in the progress of private knowledge towards public knowledge. On the other hand, how Simpson's work on fluxions took shape between 1737 and 1750 entails the study of circulation, interpretation and actual use of

MATHEMATICAL KNOWLEDGE IN NAVIGATION; EXPLORING THE TRANSFER OF SKILLS IN THE YEARS UP TO THE ALMANACK

Jane WESS
The Science Museum, London, THE UNITED KINGDOM
jane.wess@nmsi.ac.uk

Abstract

It is well-known that one of the major drivers for mathematics in the 18th century was the demand for improved navigation. While the history of the chronometer method has received the most attention, the astronomical methods have also been lucidly documented particularly by Derek Howse and Allan Chapman. Mary Croarken has provided a lively account of the compiling of the Nautical Almanack during the last third of the century. There have also been studies undertaken on mathematical education aimed at aspiring navigators, and contemporary texts are available. In addition to written material, 18th century navigational aids, including mathematical rules, abound in all major collections of scientific instruments.

This paper aims to bring these components together to explore how the mathematical skils necessary for improved navigation were transferred and disseminated, taking as a starting point Samuel Newton's An Idea of Geography and Navigation... *of 1695, and an end point the stable running of the Almanack computations achieved around 1789. It will explore where the expertise resided at different times, question how this expertise was used and communicated, and note any shifts in the skilling or de-skilling of navigators. It will also aim to incorporate the role of the leading mathematicians, and those with commercial interests represented by the East India Company and the Merchant Adventurers.*

First a quote from Isaac Barrow from *The Usefulness of Mathematical Learning Explained and Demonstrated…* 1734:

> 'We may be said to receive from the mathematics increase of fortune, convenience of labour, we have a safe traffic through the deceitful billows, pass in a direct road through the tractless ways of the sea, and come to the designed Ports by the uncertain impulse of the winds'.

But on the other hand, from Richard Norwood in *The Seaman's Practice* of 1712:

> 'Mathematics affords large fields of delightful speculations wherein a man might walk far with much pleasure, but if from so many fair flowers he brings home no honey, if he brings not from these

> speculations some useful practices, neither himself or others are likely to receive much Fruit from them.'

The 'unreasonable effectiveness of mathematics'[1] here given an early airing by Barrow, has become an established dictum in the late 20th and early 21st centuries. However, this paper argues that mathematics had to struggle to become central to the crucial practice of navigation in an era still very much early modern, where mathematics was a fledgling component of practice, showing potential but gaining ground only gradually. While some historians, particularly those closest to the practice, consider navigation to be an art[2], most tell of the 'science' of navigation and most put the start of scientific navigation with the advent of the Almanack.[3] Obviously these developments, from intuition to a reliance on a mathematically-based procedure, were not instantaneous or without problems.

This paper will endeavour to link the instruments in our collections in the Science Museum, London with four other aspects of navigation: commercial interests, contemporary elite mathematicians, the mathematics taught to navigators as evidenced by the texts, and actual practice.

Commercial and National interests

We can connect the mathematisation of navigation in the desire to find Longitude, with the improvements necessary for the development of Britain as a nation state. John Gascoigne has documented the increasing role of the Royal Society in government in *Science in the Service of Empire*[4] The influence of commercial interests specifically in navigation in England during the century from 1670 is apparent in the setting up of Greenwich Observatory, the Christ's Hospital Mathematical School, the Longitude prize, the Smith Prize, and the well-known multiple purposes of Cook's voyages. This was a period when according to Andrew Lambert[5], Britain was starting to benefit from a Tudor decision to become a maritime nation. Besides the national interest, the vast British East India Company with tax-collecting rights and a large army, was commissioning ships at a rate of 30 a year in the mid 18th century and did not want to lose them or their precious cargos. The rate of construction and size of the vessels was such that it threatened the Navy's ability to obtain good oak wood for their own ships.[6]

The 'Mathematicians of the First character'[7]

The above is a phrase from the preface of Isaac Newton's *A Treatise on the Method of Fluxions and Infinite Series* (1736). The major players were Isaac Newton, Edmund Halley, John Flamsteed and Leonard Euler, but also James Bradley and of course Tobias Mayer. There were also those endeavouring to decipher their work for able and interested audiences in England for example: William Whiston, James Gregory, James Hodgson, and Charles Leadbetter, and those who later contributed to reforming the various tables: Richard Dunthorne and Israel Lyons. The figure who eventually brought this to a conclusion was of course Nevil Maskelyne. The central concern for navigation had been long recognised as finding the longitude, and the Theory of the Moon's motion became the central issue. However, the aberration and refraction of light, and the shape of the Earth were other salient aspects of what was implicitly and sometimes explicitly seen as the problem with potential.

The start of this episode in the 'harrassment of the Moon' as Whiston charmingly put it in 1728[8] was a visit by Isaac Newton to Greenwich in September 1694 when he was shown Flamsteed's lunar data. At that time Newton felt there was just a possibility that the Moon's motion could be understood in a way which could solve the longitude problem. It is not known exactly what he was sent, but Newton was worried that Flamsteed's disclosure of his work on the Moon would show

[8] Nicolas Kollerstom *Newton's Forgotten Lunar Theory* Santa Fe N.M 2000 p.18.

he was 'trifling with mathematics.'[9] The implication from earlier historians that Flamsteed withheld data appears untrue, a ruse by Newton to disguise the fact he had made little progress. His struggle with this problem has been recounted by Whiteside, Westfall, and more recently, Iliffe. Newton is reported to have said to De Moivre that he would like to have had another go at it if he was a younger man.[10]

Newton's 'Theory of the Moon's Motion' eventually appeared in a pamphlet in English in 1702 just after it had appeared in David Gregory's *Astronomiae, Physicae et Geometricae Elementa* in Latin. It consists of a mathematical recipe without the expected philosophical causes or geometrical proofs of the Principia. It gave seven-step instructions in tortuous and opaque text for applying equations to solve the lunar longitude. It was included in a slightly different form in the second edition of the Principia in 1713, and again in the 1726 English edition, but without a specific reference to its use. The statement 'The mean motion of the moon and its apogee are not yet known with sufficient accuracy' made in 1726 begs the question, 'for what?'

Edmund Halley, another important player, investigated the Moon's motion during a complete Saros cycle of 18 years while Astronomer Royal between 1721 and 1739, with the results published after his death in 1749. He backed Newton's theory of the Moon's Motion, although he modified it, and was the first to use it systematically.[11]

Aberration of light model

James Bradley, the following Astronomer Royal, detected and explained the aberration of light, using a model in the Science Museum's collections to demonstrate the phenomenon using two simultaneous motions. He had been working on the problem of lunar parallax in 1727, and reported his findings in the Philosophical Transactions the following year.[12] 'The sine between the real and visible place of an object will be to the sine of the visible inclination of the object to the line in which the eye is moving, as the velocity of the eye to the velocity of light'. It is said he was boating at the time when he realised what was happening.[13]

However, it is well-known that for the eventual compilation of the Almanack, Maskelyne used data provided by Tobias Mayer of Gottingen, based on the methods of Leonard Euler, although these in turn owed much to Newton's work. Mayer in his letter to Euler of 4th July 1751 said 'Your tracts on analysis and mechanics, honerable sir, have enabled me to study the Moon's motion according to Newton's theory.'

Mayer was first and foremost a surveyor who wanted to establish better co-ordinates for terrestrial locations.

Tables and texts

About 30 texts, published between 1680 and 1780 for the instruction of seamen, have been studied, and many more exist.[14] Most contain some sort of tables even if only for meridional parts, (that is, the adjustment to be made for the spherical nature of the Earth) Mostly they are fairly basic and changed little during the period. The vast majority follow a similar path, through plane trigonometry to plain sailing, where no account is taken of the spherical, never mind spheroidal, nature of the Earth. After that comes parallel sailing, mid-latitude sailing, the use of the Mercator chart, and the more complex traverse tables.

The attitude towards sailing by any other means than dead reckoning was often disparaged in the earlier part of this century, but even when not actually dismissed, longitude by celestial observation was not generally tackled, other than by giving a list of the possibilities.[15] On the other hand latitude was usually listed as one of the three 'knowns', which were direction from starting point (course), distance from starting point (departure), and latitude. Latitude was the piece of information requiring astronomical observation. The calculations involved in plotting a traverse table, i.e. a summary of the various courses and distances the ship had travelled over a period of time, were tedious in the extreme.

Samuel Newton has been chosen here as the author to represent the many text writers producing manuals for the seaman in the period under consideration, hence a 'Tale of Two Newtons'.

[15] Samuel Newton *An Idea of Geography and Navigation* London 1695 p. 79 and James Hodgeson *A System of the Mathematics* 1723 .p.375 'when a good theory of the Moon can be obtained'.

While Isaac was concerned with the spheroidal nature of the Earth, Samuel tells his readers that the Earth is 'not flat but spherical'. Like most others of this period he states that the difference of Longitude, which was what was normally measured rather than an absolute longitude, could not be measured by celestial observation. He lists eclipses, satellites of Jupiter, a clock,or the Moon as possibilities but then says, reasonably, 'I wish any of them could be put into practice at sea.'[16]

Samuel was Master of the Mathematical School at Christ's Hospital as were James Hodgson and John Robertson more successfully later in the period. This was a crucial institution without parallel in its role in the training of young navigators. However, the low level of performance has been studied by Robert Iliffe.[17] Samuel Newton was thought to have a good character and was supported by Isaac for the post, despite being considered inferior in some respects.[18] The school was found wanting by critics, who believed more should be required of the boys.[19]

As well as Christ's Hospital and the military schools at Woolwich and Portsmouth, navigation was starting to be taught at the coffee houses in London, courses in geometry and spherical trigonometry were taught by John Harris from 1707.[20]

Instruments and instrument makers

These played a vital part, as measuring and calculating tools but also as objects of status. Edmund Stone in the translators preface to *The Construction and Principal Uses of Mathematical Instruments* of 1758 says of instruments: 'They connect, as it were, the Theory to the Practice, and turn what was bare contemplation to the most substantial uses' The most important calculating instrument for navigation was the 'Gunter'. Observational instruments employed on land by elite astronomers were essential to table construction but are outside the scope of the paper.

Instruments for the seamen employing dead reckoning consisted of the log line for distance, which were becoming more 'scientific' during the period.[21] There was a compass for direction and hour glasses for time. In the earlier part of the period a back-staff was used for altitude of the stars, or more often Sun. After 1732 invention of the reflecting quadrant allowed easy use at sea by bringing the Sun or observed celestial object in contact with the horizon by means of double reflection. The movement of the ship was thus avoided. Writers after this date tend to recommend it above others.[22] When the horizon was not visible the octant could be used with an artificial horizon which acted to reflect the Sun from a horizontal surface, so the final reading would be halved.

Mayer himself proposed a circle with a repeating principle, but this was found not to be as useful as the octant at sea on a crucial test by John Campbell in 1756, when Bradley asked the Board of Longitude if Campbell could test Mayer's tables and circle. Campbell suggested the sextant, made of brass with a scale of 60 degrees, it combined the best of both instruments and became the fundamental observing tool on board ship for two hundred years. Other ways of determining longitude were also proposed, especially the magnetic variation by Halley, which gave rise to beautiful instruments such as the dip circle and meridional compass, and the well-known variation charts

Much more important mathematically was the 'Gunter', which was a considerable modification of the plain scale by Edmund Gunter, who put John Napier's logarithms onto a line soon after their discovery in about 1620. There was also a sliding Gunter, particularly advocated by William Mountaine[23] which does not appear to have been so successful in this period.

The Gunter contains a number of standard lines which are on the 'plain' side: rhumbs, which are the eight compass points in a right-angle, chords, tangents, sines, a line to give the length of a degree of longitude for various degrees of latitude. On the Gunter or logarithmic side: sine of the rhumbs, a logarithmic line, sines, cosines, and secants on the same scale, versed sine, which is one minus the cosine, tangents, the meridian line which is used with the Mercator chart, a

logarithmic line of square roots and a logarithmic line of numbers cubed. Distances were taken off using dividers, and all problems were solved on the basis of the proportional 'rule of three.'

The problems were all to do with dead reckoning; that is with plane trigonometry. The 'cannons', or proportional rules, were sometimes set out on the instrument. The first is: 'As the Radius is to Distance so is the sine of the course of departure, and so is the sine complement of the course to the difference of latitude.' This is followed by three similar cannons to do with finding latitude, mid latitude sailing and using the Mercator chart.

Practice

It is difficult to establish how the various types of ship were actually navigated during this period. Historians complain of a backward culture[24] and many contemporary writers and mathematicians complain of the difficulty in teaching new methods to seamen. Halley wrote to Pepys complaining that 'obstinately they resolve to make use of no other than the plain chart.'[25] As late as 1773 we find William Puddicombe saying 'the manner of keeping a reckoning by our English navigators is by the log line and half minute glass'.[26] After 1767 when with the appearance of the Almanack we might expect a change in the texts, no such paradigm shift appears and they continue in similar vein[27].

P.C.H. Clissold[28] describes a ship's log relating a journal for a voyage in 1704 in the George from The Lizard on the south west tip of England, which was a popular reference point as it was taken as being 50 degrees north, to Madeira. We learn that East Indiamen and King's ships i.e. the Navy, took logs every hour, but Merchant ships every two. There is a traverse table constructed from the compass and log lines and variation is recorded. The log books start with plane trig problems and the tangent formula written out in words. All information points towards the maths being used being what was necessary for dead reckoning- long and laborious trigonometry.

Links between commercial interests and texts

The commercial and national interests are often specifically referred to in the texts. An early example is Matthew Norwood's *System of Navigation* of 1685: 'I have endeavoured to promote and advance a Science wherein the Safety, wealth and Glory of the English Nation is so much concerned'. Francis Cawood in *Navigation Completed…* of 1710 writes 'Among the useful arts none is so beneficial to your Majesties Dominions as the improvement of navigation' and in a poem 'Longitude Discerned' writes:

> 'To make her ships on all known shores soonest seen
> And unknown Worlds obey Great Britain's Queen'

An example of direct commercial interests in producing the texts can be found in the East India Company's endorsement of Maskelyne's recommendation for the Nautical Almanack in 1765.[29] Maskelyne also had considerable help from the East India Company in setting up the observatory on St Helena in 1761, and The Royal Society thanked them formally.

Links between commercial interests and instruments

These links can be seen at many levels. By the early 18th century there was a thriving trade in London of makers producing 'mathematical instruments', anything used for measurement for those in trade. On a national scale, any instrument which could deliver improved navigation was greatly valued, the development of the chronometer and sextant being the prime examples. At the end of the period under discussion sextants were starting to be produced by machine by the dividing engines of Jesse Ramsden and Edward Troughton, so instruments became 'off the peg' commodities. Simon Schaffer has recently made a direct connection between Empire building and the use of instruments across the globe, where they played a role in establishing authority and superiority.[30]

[30] Simon Schaffer 'Expeditions and Empire' talk at the National Maritime Museum, Greenwich, October 28th 2010.

Links between texts and the instruments

Some texts such as that by Benjamin Donn, explicitly promoted a particular instrument.[31] More usually the texts include descriptions of the Gunter in general increasingly from the mid 18th century, for example John Robertson in 1754 and William Mountaine in 1778. It appears the Gunter did not fall out of favour until the 1840s.[32] These books solve problems with the Plain sailing using geometry, and then by the Gunter.

Links between the texts and practice

W.E. May, a practical seaman and historian complains of 'works on navigation clogged with much mathematical material, of no real value to the seaman.'[33] In the early part of the period E.G.R. Taylor relates that Samuel Pepys had said that the ship's captains were dismissive of the mathematical boys, and for their own safety they had to be shipped in pairs.[34] In the later part, a report by Alexander Dalrymple, then a passenger in the Grenville crossing the Atlantic in 1775 says that lunars were taken, but relying on this method resulted in being half a degree (more than 30 miles) too far East, as there was no visibility for several days.[35] A movement towards mathematisation had taken place, but the outcomes were still far from guaranteed.

The text to break the mould was Maskelyne's *The British Mariner's Guide* of 1763, where for the first time, the use of lunar distances to find longitude was advocated for the ordinary seaman. 'They will be found much more easy and concise than any yet proposed' claimed Maskelyne for his instructions on how to proceed. But they were very far from easy or concise. The fact that the first edition of the Almanack had sold 10,000 copies by 1780 is misleading regarding its use because they were supplied to all the Navy's ships in 1767.[36]

Links between instruments and practice

We know a lot about the experimental use of the pioneers –John Campbell with the reflecting circle and quadrant, and Maskelyne with the sextant, but less about ordinary use. In our collection at the Science Museum there are a number of wooden octants dating from well after the invention of the sextant, showing that new instruments had a long gestation period before being accepted. While the Gunter was invented in 1624, it was still growing in use in the mid 18th century. Puddicombe writing in 1773 says 'Perhaps it may be thought I too much prefer the Gunter to the more correct method by help of logs (tables?), but as these are seldom used at sea…'

Links between elite mathematicians and the texts:

Flamsteed's *Doctrine of the Sphere* was incorporated into Jonas Moore's *New System of the Mathematicks* in 1681, and Newtonian-based discussions of the mean motion of the Moon featured in the works of Whiston, Dunthorne, Leadbetter and Halley, but these were not texts for navigators. The vast majority of texts don't mention the elite mathematicians at all. They are using methods which do not require the new mathematics of the late 17th and early 18th centuries. It was not necessary to have understood fluxions, series, or be able to manipulate algebraic equations. It was necessary to have a good grasp of plane and spherical trigonometry, and an ability to use logarithms either in table form or by the Gunter. Only a small minority of the text writers include concepts and mathematics on a higher plane than that necessary for dead reckoning.[37]

Links between commercial interests and elite mathematicians

It is entirely to be expected that commercial interests would chime with the desire to save souls at sea, and would support and stimulate the elite mathematicians. However, desirous outcomes were partly thwarted by two opposing factors: underfunding of practice and over-concentration on a big prize. It is well-known that Flamsteed had to buy his own instruments for Greenwich and his widow took them away when he died. It is also well-known that a similar situation occurred with Bradley's results which Maskelyne endeavoured to recover for Greenwich. Maskelyne lamented that by the loss of these observations 'the improvement of astronomy has been kept 50 years behind.'[38] While Tobias Mayer had great support from Euler, it has been suggested that Halley kept his methods secret, presumably because he had an eye on the prize money, and he has also been accused of delaying publication in order that others should not use his data.[39]

It is interesting to note Morris Kline's view.[40] 'He believes 'mathematics is first and foremost a subject to solve problems in the physical world.' Were Newton and his contemporaries at the end of the 17th century working towards solving the Longitude, which at that time seemed so remote? Kline says 'Because they were great they could discern directions of investigation which must ultimately prove significant.'

Conclusions

There are some long-held views of this episode which have been promulgated by a series of historians which now need to be challenged.

The first is that the Almanack changed everything. Derek Howse claims that 'a very high proportion of the world's deep sea navigators began to … (use the Almanack) … from 1767.'[41] However, while 10,000 copies were dispersed by 1781, it is extremely unlikely they were used. The Almanack is not mentioned in the navigator's textbooks of the time.

The second is that the Almanack was easy to use, an error made by taking the word of the person who was promoting it. Maskelyne's assertion that 'it demands only care in the computer and no knowledge of spherical trigonometery is economical with the truth.

The third is that the tables did away with the most time consuming and difficult parts reducing the time from 4 hours to 30 minutes.[42] Yes if you were Maskelyne, Captain Cook or John Campbell, but otherwise you were not using the lunar distance method. The impression that this was somehow standard practice is very misleading.

The fourth is that seamen were backward. It may be that practitioners take up new methods slowly, but in fact, as Thomas Haselden put it in 1722 'Navigation is no trifling knowledge', never mind the lunar distances. Using plain trigonometry, sometimes with the Mercator chart, following through the individual problems with the Gunter to form a traverse table to produce the days work is not elementary.

So, the conclusion is that there was considerable skill in navigation which became increasingly mathematical in this period, not through the use of lunar distances but through gradually improved teaching by means of schools, lectures and texts in the more routine but considerably demanding methods. The use of instruments such as the Gunter necessitated conceptual understanding and could not be done just by rote. The increased use of the Gunter, if we go by the texts, indicates increased practice of calculation where there was very little before, not an increasing reliance on rules. The dream of lunar distances, more than any other mathematical/astronomical method, was to stimulate new mathematics in the shape of what we would now call perturbation theory, which eventually fed into the tables and would eventually change practice in the future.

BRITISH INFLUENCES IN THE INTRODUCTION OF CALCULUS IN SPAIN (1717-1767)

Elena AUSEJO
Universidad de Zaragoza, SPAIN
ichs@unizar.es

Abstract

It is well known that military men and Jesuits are the main characters of the process of introduction of calculus in Spain. The first documentary evidence of a Spaniard on Calculus appears in 1711 with the name of Francisco Argáiz de la Torre, who submitted his thesis at the University of Toulouse, under the direction of the Jesuit Jean Durranc. The reorganization of the colleges after the expulsion of the Jesuits (1767) marks the end of a first stage in this process from an educational point of view, and it focused on teaching institutions and textbooks.
During this period, calculus was taught in Madrid at the Real Seminario de Nobles *and at the* Colegio Imperial*, at the* Colegio de Nobles de Cordelles *in Barcelona (all Jesuit), as well as in the Navy, but it was not taught neither in universities nor in the Army.*
Within the framework of Newton's De methodus fluxionum *[1740], the two main influential British textbooks were MacLaurin's* Treatise of fluxions *[1742] and Simpson's* Doctrine and Applications of Fluxions *[1750]. The former was used as a basis by Pedro Padilla. a military engineer, to write* De los cálculos diferencial e integral o méthodo de las fluxiones *(1756), the only textbook on calculus actually printed in this period – that was used at the short lived* Academia de Guardias de Corps *(Corps Guards Academy). Simpson's work was re-elaborated by the Jesuit Tomás Cerdà in differential notation, and was probably used at the Colegio de Nobles de Cordelles and at the Colegio Imperial. It is also worth mentioning that Cerdá was a disciple of the Jesuit Esprit Pezenas, MacLaurin's translator into French (1749), and the most probable source of Padilla who, by the way, also referenced Simpson in his book.*

The introduction of infinitesimal calculus in Spanish teaching institutions (1717-1767)[1]

Jesuits

Although Francisco Argáiz de la Torre, the first Spaniard active in calculus, was a pensioner at the Jesuit College in Toulouse, and his thesis on infinitesimal calculus was presented at the University of Toulouse in 1717, under the direction of the Jesuit Professor Jean Durranc, there is no further evidence of Jesuits on calculus in Spanish institutions until 1751, when one single student of the Real Seminario de Nobles took part in the first public *Mathematical Conclusions* (Jesuit contests) that included differential and integral calculus, under the direction of Father Esteban Terreros, professor between 1746 and

[1] An extensive and in-depth discussion on this subject, as well as further detailed references, can be found in [AUSEJO & MEDRANO, 2010].

1754 [UDÍAS, 2011; 2010, p. 26]. Again in 1760, two students took part in public Mathematical Conclusions which included differential calculus, this time under the direction of Father Esteban Bramieri, professor between 1757 and 1767 [UDÍAS, 2010, p. 26]. Finally, in 1764 two students took part in examinations also including integral calculus. Although no textbook was published either by Terreros or Bramieri, and no manuscript has survived, the presentations show that teaching followed the infinitesimal trend.

The situation was different at the Colegio Imperial, where Terreros was transferred from 1755 until 1767. There he taught between 1755 and 1760 [UDÍAS, 2005] with Father Johann Wendlingen (1750-1767). From 1761 onwards, Christian Rieger (1761-1765), Miguel Benavente (1761-1767), and Tomás Cerdá (1765-17167) were active professors alongside Wendlingen [UDÍAS, 2010, p. 26]. It turned out that around 1761 hard criticism emerged against the level and quality of mathematics at this college –especially against Wendlingen–, and the lack of public conclusions and published mathematical courses were specifically censured. As a matter of fact, the only public conclusions of this period –which included no calculus–, seem to be those of 1762, under the direction of Benavente.

As regards editions of courses on mathematics, the balance sheet is not better. Among the professors of the Colegio Imperial, only Wedlingen and Cerdá published on mathematics, both of them on elementary mathematics. Nevertheless, the latter left unpublished manuscripts which prove his mathematical skills, while the former report on Lucuze's memoir on the inclined cone surface shows his wide gaps on infinitesimal calculus.

Concerning manuscripts, the situation is more interesting, since the Spanish Royal Academy of History keeps an anonymous forty-two page (in quarto) Latin manuscript on fluxional calculus; a *Complete Course on Mathematics,* probably authored by Rieger and Benavente, that includes a seven chapter (twenty-eight pages in folio) *Easy Introduction to the Algorithm of Fluxions* ; and a treatise on calculus, possibly the one which Cerdá announced in his *Liciones de mathematica* (1758), which is a re-elaboration in differential notation of Simpson [1750], except for Sections I, XI and XII of Simpson's First Part and Section IX of Simpson's Second Part. There is no evidence of Terreros and Wendlingen teaching calculus between 1755 and 1760, therefore calculus perhaps was taught at the Colegio Imperial from 1761 onwards by Rieger, Benavente, and Cerdá. The latter maybe also taught calculus at the Seminario de Nobles de Cordelles in Barcelona, from 1758 or 1760 until 1764.

Military men

Two military teaching institutions, the *Real Academia de Guardiamarinas* in Cádiz (Midshipmen Academy) and the Corps Guards Academy, also introduced calculus by the mid-eighteenth century.

Jorge Juan was the director of the Midshipmen Academy as of 1751. He was a great supporter of infinitesimal calculus and, as it will be shown in this paper, a key figure in the process of the introduction of calculus in Spain. His *Observaciones Astronómicas y Físicas* (Physical and Astronomical Observations) used infinitesimal calculus already in 1748. After the French astronomer Louis Godin was appointed Director by Jorge Juan in 1753, the exams of 1754 prove the actual teaching of calculus.

The short-lived Corps Guards Academy (1750-1761) closed due to lack of students (only three studying sciences in 1758), but in the meanwhile its Director, military engineer Pedro Padilla, must have taught calculus, since Silvio Panego, one of the eight students taking the exams of 1752, disserted on this matter. Moreover, Padilla published between 1753 and 1756 four volumes of a Military Course on Mathematics to be used at the Corps Guards Academy [PADILLA, 1753-1756], whose fourth and last volume –namely, *De los cálculos diferencial e integral o méthodo de las fluxiones* (1756)– was devoted to fluxional calculus. Based on MacLaurin's *Treatise of fluxions* [1742], this textbook also includes references to Wolf and to Newton's book on fluxions –that is, the French translation of *De methodus fluxionum* by Buffon [NEWTON, 1740].

On 18 May 1756, Padilla's treatise on fluxions obtained Jorge Juan's approval. As a matter of fact, there existed a governmental concern about the need to produce good modern treatises and textbooks on mathematics in Spanish. For this purpose the Count of Aranda, General Director of Artillery and Military Engineers, promoted in 1755 the foundation of the *Real Sociedad Matemática Militar* (Military Mathematical Society). Although no volume of a treatise on mathematics had been published when the Society was wound up in 1760, it is worth mentioning that military engineer Antonio Córdova included series and calculus in the table of contents of the volume devoted to algebra. Nevertheless, military engineer Carlos Lemaur, who was in charge of the volume on Mechanics, published in 1778 a book titled *Elements of Pure Mathematics* in two volumes –to be used at the Military Engineers Academy– which included no trace of calculus. Actually, it seems that the ineffectiveness of this institution is somehow related with differences between Lemaur and the Director of the Military Mathematical Society, military engineer Pedro Lucuze.

Lucuze also directed the Military Engineers Academy from 1738 to 1779. No calculus appears in the manuscript lecture notes either by the Academy students or by Lucuze himself, although he kept notebooks on calculus among his private papers, and even produced a memoir on the inclined cone surface. The same policy was followed by Juan Caballero and Miguel Sánchez Taramas, the Directors who followed him. Despite severe criticism from military engineer Tadeo Lope y Aguilar in the eighties, they only considered the possibility of introducing a summary of calculus, convinced as they were that extensive and deep study was unnecessary for military engineers.

Similarly, when in 1767 four students of the Artillery Academy asked to be taught fluxional calculus, their Professor of Mathematics, Lorenzo Lasso, expressed his opposition to higher mathematical instruction for artillerymen. Actually, the Mathematical Course for Military Instruction (*Curso Mathematico para la instrucción de los Militares)* by the former and first Professor of Mathematics of the Artillery Academy, Jesuit Antonio Eximeno [UDÍAS, 2010, p. 19], did not include calculus.

As a matter of fact, calculus was not included in the syllabus for artillerymen until 1795, and in the syllabus for military engineers until 1803.

It is worth mentioning that the libraries of the Corps Guards Academy, the Military Mathematical Society, and the Military Engineers Academy kept, together with continental bibliography on infinitesimal calculus, British references. Besides Newton [1740] and MacLaurin [1742], Saunderson's *Elements of Algebra* (1740) could be found at the Military Mathematical Society and the Military Engineers Academy. The latter also owned Edmund Stone's *The Method of Fluxion* (1730) and Benjamin Martin's *Philosophia Britannica, or A new & comprehensive system of the Newtonian Philosophy, Astronomy and Geography* (1747), while the Corps Guards Academy kept the *Philosophical Transactions* of the Royal Society and Wallis *Opera mathematica* (1693-99). Curiously enough, none of these libraries owned Simpson [1750].

British influences in the introduction of infinitesimal calculus in Spain (1717-1767)

The failure by Spanish universities to assimilate new scientific ideas, their commitment to scholastic ideas, and the lack of financial support for chairs of mathematics and physics, eventually left them on the wayside of scientific teaching.

All attempts to introduce infinitesimal calculus in university curricula, as well as the endeavours to reform a teaching system that was not useful for the Crown's plans, failed throughout the 18th century. This led the government to turn to those parts of society that were not hampered by the *historical* drawbacks typical of University, and who were more inclined towards modern science. Only the Jesuits and the Army were capable of channelling the new science and ready to solve very pressing problems, such as the training of technicians and the education of the leaders.

As far as infinitesimal calculus and, thus, mathematical modernity are concerned, we can state that the expulsion of the Jesuits unquestionably cut short any modernization plans that might have been undergoing implementation. Nonetheless, the four decades that elapsed between these frustrated plans and Argaiz's thesis do not place the Jesuits at the forefront of mathematical knowledge in Spain. Moreover, there is no official policy aiming at the promotion of scientific knowledge. Their influence in the introduction of modern mathematics in Spain is really modest: calculus is adopted only during the final decade of its presence in Spain, with a very limited audience –we only know of five students at the high mathematical level–, and no published textbooks on calculus, which survive only as manuscripts.

As for the education given by the Army, the assessment one can make of the military institutions over this period is definitely poor. We have proof that it was taught at the short-lived Corps Guards Academy and at the Midshipmen Academy, but we also know for a fact that it was missing at the Artillery Academy, and we are already in a position to establish almost definitely that it could not be set up at the Military Engineers Academy who, unlike the Navy, faced greater difficulties to appreciate the significance of the practical side of the new calculus. In fact, from that moment on we can identify positions that were totally contrary to its introduction (Lorenzo Lasso, Juan Caballero, Sánchez Taramas, and Carlos Lemaur) in the context of an internationally persistent debate throughout the history of engineers' training: their mathematical education. Thus, due to the failure of the fleeting Military Mathematical Society to develop a thorough mathematical monograph, including infinitesimal calculus, the first and only textbook on calculus for that period is Pedro Padilla's.

However, it is worth mentioning some significant developments in the process of the introduction of calculus in Spain: 1) institutional support, embodied in the Count of Aranda –Jorge Juan tandem that, nevertheless, only produced results in the Navy, Jorge Juan's direct influential realm; 2) updated bibliography accessible through the institutions –at the Corps Guards Academy, at the Military Mathematical Society, and at the Military Engineers Academy; 3) educated promoters – even if they failed in their publication attempts, like Tadeo Lope and Antonio Córdova.

Jorge Juan is especially noteworthy, as he was the designer of the renewal and improvement of the syllabus of the Midshipmen Academy, the author of textbooks to be used therein –such as the *Compendio de Navegación* (1757)–, the founder of the Astronomical Observatory of Cadiz, the importer of foreign scientists (Godin), the promoter of new textbooks (Padilla), and possibly responsible for collecting the Military Mathematical Society library.

Significant is also the institutional concern with teaching, and particularly the production of textbooks, which incidentally was also an unresolved problem around the world. In the 19th century it was not difficult to find inspiration from abroad, especially France, for textbooks aimed at the mathematical training of different groups, but in the 18th century, the very same concept of textbook was under construction. This accounts for the initial preference for the fluxional approach, which evolved towards infinitesimal trends through the century.

The systematic collection and analysis of teaching materials from Spanish teaching institutions –manuscript courses, examinations and textbooks– enables us to conclude that the main trend in the introduction of calculus was fluxional (Padilla, Rieger-Benavente, Cerdá), although references to the differential approach exist (Argaiz, Jorge Juan, Bramieri, Cerdá's notation), and it might well have been the need to produce textbooks in Spanish which led to the fluxional approach through the appropriation of English works.

As far as cultural transfers are concerned, it is important to stress the appropriation of English texts (McLaurin, Simpson) within a socio-political and cultural context that has so far been traditionally considered under French influence. This is especially striking when reviewing the questionable decline of 18th century British mathematics which, at least in Spain, seems to have gone unnoticed.

For instance, Jesuit Cerdá and military engineer Padilla appear strangely connected through Father Pezenas: Cerdá was Pezenas' disciple, and Padilla probably used Pezenas' translation into French (1749) as the basis for his volume on calculus; in this work, Padilla referred to Simpson [1750], the treatise on calculus Cerdá chose to re-elaborate in differential notation. Both authors use English fluxional works, but Cerdá shows he does not find any contradiction in using fluxional concepts together with differential notation.

Actually, differences between fluxional or infinitesimal approaches do not seem to be so important for Spanish authors in this period. By the end of the 18th century, Leibniz's notation was absolutely dominant, but fluxional concepts were still considered more rigorous –a position that appears in authors such as Bails, Juan Justo García, Ciscar, Chaix, and even Vallejo.

In view of the above, whilst in Spain, during the half century elapsed between 1717 and 1767, calculus was taught at the Real Seminario de Nobles –and perhaps also at the Colegio Imperial and the Seminario de Nobles de Cordelles– and in the Navy, it was ignored by both the specialized bodies of the Army (military engineers and artillerymen), and by the universities, and only one textbook on calculus was published. In such circumstances, and given the uphill battle, we should admire what was achieved after all, though we cannot really affirm that calculus was fully introduced during this period –not even in the Jesuit and military environments–, nor consider that the country acceded to mathematical modernity, and certainly not identify the Jesuits and the military as the authors of this accession.

These facts confirm that also in Mathematics Spain's accession to the enlightened process started during the second half of the 18th century, and that the first tangible results were obtained only during Charles III's reign. The best was still to come. Starting over, though not from scratch, by setting up the colleges and seminars abandoned after the Jesuits' expulsion eventually facilitated the emergence of a series of teachers and institutions that gave a new impetus to science teaching in Spain and allowed a certain blossoming of mathematics during the following period, up to the Independence War (1808-1814).

Conclusion: the civil way

Since 1757 the Count of Aranda also headed, as *consiliario*, the *Real Academia de Bellas Artes de San Fernando* (Royal Academy of Fine Arts of San Fernando). In 1759, he proposed a reform of the Architecture syllabus, insisting on the need to have good textbooks in Spanish and to include mathematics.

Not much had been done in that area when Jorge Juan was appointed honorary fellow in 1767. He started by rejecting in 1768 the Treatise on Geometry and Arithmetic by José de Castañeda, and that very year Francisco Subirás and Benito Bails were appointed Professors of the two new chairs of mathematics. The latter accepted nomination but Subirás, who had studied at the Seminario de Nobles de Cordelles with Cerdá and was teaching architecture in Madrid since 1764, rejected the appointment in order to go back to Barcelona as Director of the Seminario de Nobles de Cordelles. It should be noted that both chairs were independent from the three Sections of the Academy –painting, sculpture and architecture.

Besides teaching, Bails was commissioned to write a textbook on mathematics under the direction of Jorge Juan. As demanded in 1759, he was asked to translate, extract and summarize the best available European works in two different monographs: *Elements of Mathematics,* a complete mathematical treatise in ten volumes [BAILS, 1772-1783]; and *Principles of Mathematics,* a more elementary and concise treatise in three volumes [BAILS, 1776].

Bails's work plan of December 26, 1769 for the *Elements* included differential calculus – "*taken from Euler and L´Hôpital*"– and integral calculus –he pointed at MacLaurin, Bernoulli, Euler and Jaquier as possible sources. As regards the *Principles,* infinitesimal calculus was included in the second volume from the second edition (1789) onwards. Both works were the first widely circulated textbooks in Spanish extensively dealing with infinitesimal calculus, which was thereafter progressively considered in higher education.

As for British influences, the powerful influence of Jorge Juan definitely tipped the scales in favour of continental calculus. For instance, Subirás explains he uses infinitesimal calculus, despite his preference for the principles of fluxional calculus, in order to follow Jorge Juan's method [SUBIRÁS, 1776, p. VII]. The same position is to be found in Gabriel Ciscar's enlarged re-edition of Jorge Juan's *Examen Marítimo* [Ciscar, 1793, p. VII][2].

Abstract

This article presents an historical approach to the introduction of the elementary divisor theory in Spain. It aims at answering the question: When did this theory first appear in Spain? We will try to answer this in two different settings, with attention both to research, and teaching. We will refer mainly to teaching because it is there that the main activity was produced.
Although the origins of the elementary divisor theory are seen in the work of other authors, it is well-known [21] that this theory was consolidated by Weierstrass in his work (1868) about bilinear and quadratic forms [32].

In the early 20th Century

The 20th Century in Spain began with significant efforts in education and scientific policy to achieve European standards. In 1900 there was a great educational reform promoted by the Minister of Public Instruction and Arts, Antonio García Alix (1852-1911). In terms of research, we can mention the creation of public and private institutions such as the Junta para Ampliación de Estudios e Investigaciones Científicas (JAE, 1907) and the Asociación Española para el Progreso de las Ciencias (AEPPC, 1908), [4].

JAE awarded grants to study abroad. Its intention was to send young graduates and professors abroad to complement their academic training within their respective disciplines and to promote their research skills. This institution founded several centres in which the grantees could continue working and create a school, for instance a biological research laboratory and an automatics laboratory. Julio Rey Pastor[1] (1888-1962) studied in Berlin (1911-12) and Göttingen (1913-14) with a grant from JAE, became the director of research in the then called Laboratorio Seminario Matemático (LSM, 1915).

On the other hand, the AEPPC had the intention of spreading the knowledge by means of scientific conferences and supported a new institution, the Sociedad Matemática Española founded in 1911.

[1] In 1913 he became a professor of Mathematical Analysis at the Central University of Madrid, [30, 15].

With respect to teaching, the following chart shows the official syllabus for mathematics in 1915, wherein the subjects Elements of Infinitesimal Calculus, and Celestial Mechanics were introduced in 1909 and 1915, respectively.

Table 1: García Alix's plan for Exact Science Degrees. Syllabus (1915).

1	2	3	4	**Doctorate**
Metric Geometry	Analytical Geometry	Geometry of position	Decriptive Geometry	Higher Studies of Geometry
Mathematical Analysis, 1st	Mathematical Analysis, 2nd	Elements of Infinitesimal Calculus	Complements of Infinitesimal Calculus	Higher Analysis Course
			Rational Mechanics	
General Chemistry	General Physics	Cosmography and Physics of the Globe	Spherical Astronomy and Geodesy	Celestial Mechanics
				Solar System Astronomy

At that time there were three centres for studying Exact Science in Spain: Barcelona, Madrid and Zaragoza. A Ph.D. in Exact Science was offered only in Madrid. Professors in the other cities were usually interested in moving there.

The plan for mathematics was designed under the direction of Eduardo Torroja[2] (1847-1918) and was assisted by Miguel Vegas Puebla-Collado[3] (1856-1943). This syllabus was called the "plan of the geometries" by opponents, due to its excessive content of synthetic geometry. All geometric subjects for that degree were synthetic, except for analytical geometry. The synthetic geometry was also predominant in Ph.D. studies and analytical geometry was merely used to give an algebraic version to the synthetic theory. Geometric doctoral theses presented during these early years of the 20th century had a particular characteristic: if theses dealt with synthetic geometry, they received a higher mark than if they dealt with analytical geometry, [14].

Among the opponents to this syllabus we primarily find Zoel García de Galdeano y Yanguas[4] (1846-1924) who was described by Rey Pastor as "hard-working paladin of modern mathematics in Spain"[5]. Rey Pastor was right: Galdeano was a great proponent of European mathematics during his time in Spain. In 1907, he published a book as a concise setting out of mathematical topics that were omitted in the Spanish syllabus, in his words, [20, p. 6], "what we must do, is what is left out of our syllabus".

In that book, elementary divisors were quickly mentioned, [20, p. 195], as follows:

> Also the elementary divisors, which are irrational invariants of pencil forms, are valid as a criterion for their transformation. Thus, in order for a couple of pencils to transform from one into another, it is necessary that the corresponding determinants have the same elementary divisors. Weierstrass and Kronecker were the first ones devoted to these investigations.

Analytical geometry was subordinated to synthetic geometry, and mathematical analysis had little progress.[6] For these reasons the elementary divisors appeared later in Spanish mathematics. S. Cámara, J. Rey Pastor and O. Fernández-Baños were the first Spanish mathematicians who dealt with the topic of elementary divisors (see next section). However, their theses were related to synthetic geometry. Namely:

---

[2] He was a professor of Descriptive Geometry at the Central University of Madrid. He was a geometer who formed a school dedicated to the study of synthetic projective geometry, where he followed the work of von Staudt, [25].

[3] Vegas was a professor of Analytical Geometry in Madrid during the period 1891-1935. He wrote textbooks without considering elementary divisors.

[4] He taught Elements of Infinitesimal Calculus at the Faculty of Sciences of the University of Zaragoza (1896-1918) where Rey Pastor studied (1904-1908), [23, 22].

[5] [28, Inscription]. This and other quotes have been translated by the authors.

[6] A subject named Ordinary Differential Equations appeared in the 1931 Syllabus as Mathematical Analysis 3rd. Later, in the 1943 Syllabus, Linear Algebra appeared as part of Mathematical Analysis 1st.
